Volatile fatty acids (VFA) – applicable as building blocks in the chemical industry - can be produced through fermentation of biorefinery waste streams. The main drawbacks to be addressed are: i) inhibition of methanogenesis and chemical input for pH control; ii) product extraction from fermentation broth; and iii) steering the microbiome towards target products. All three of these key issues are tackled using membrane electrolysis coupled to an acidogenic fermenter.

1. Methanogenic activity

Chemical-free pH-oscillation for inhibition of methanogens

2. Separation of product

VFA-production

No significant influence of extraction on total production

Recovery of VFA

28.2 ± 3.8% of produced VFA extracted as acids in a clean stream with unoptimised extraction

Elongation of VFA

With extraction coupled, fermentation yields longer VFA

3. Ecology of the fermenting community

Lactobacillus spp. and *Megasphaera* sp. elongation?

H₂-driven selection of elongating species?

To be confirmed

Acknowledgments

For generously providing the thin stillage used in these experiments
