

ABSTRACT SUBMISSION FORM

Please submit your abstract online **before January, 30th**

NB: The subject of the message should begin with "Abstract, followed by the surname of the presenter". Please rename this file into: Name of the presenting author.doc. If there is more than one abstract from the same author, the name of the author should be followed by a corresponding number (maximum 2).

I prefer ☒ poster presentation ☐ oral communication

CONNECTING CRYSTAL STRUCTURE AND LUMINESCENCE, THE CASE OF $\text{SrAl}_2\text{O}_4\text{:Eu}^{2+}$

Photoluminescent materials or phosphors are ubiquitous in today's technology driven society, for example in LEDs, scintillators or safety signalling. These inorganic materials are composed of a host crystal doped with one or multiple metal ions, activating the luminescence [1]. The luminescence of the metal ion is often strongly dependent on the crystal structure of the host compound.

Upon co-doping with Dy^{3+} , $\text{SrAl}_2\text{O}_4\text{:Eu}^{2+}$ is well-known because of its persistent luminescence, i.e. it shows an extremely long lasting green afterglow. Although frequently used in safety signalling and all kinds of gadgets, the origin of the persistent luminescence is not yet fully explained [2]. More specifically, a second, blue emission band occurs at low temperature. It has been shown that this emission band is of importance in explaining the trapping and detrapping mechanism behind the persistent luminescence in this material. Different conflicting explanations for the occurrence of the blue emission are available in literature [3].

In this work, empirical models relating the luminescence of lanthanide ions with structural parameters of the host are applied to explain the peculiar luminescence in Eu^{2+} doped SrAl_2O_4 [3, 4]. It is shown that the blue and green emission bands originate from europium ions substituting two non-equivalent Sr sites inside the host crystal, even if both sites are rather similar.
