Overview of synthesized compounds	243

Summary

In many disease processes G protein-coupled receptors (GPCRs) are over- or understimulated, explaining why the pharmaceutical industry develops drugs (blockers or stimulators) to counteract this over- or understimulation. Almost half of the clinically used drugs today are interfering with GPCRs.

Chapter I gives a general introduction on GPCRs, such as GPCR structure, classification, signaling, as well as GPCR dimerization. Furthermore, an overview of bivalent ligands targeting GPCR dimers is given in this chapter, which mainly focuses on the recent studies on bivalent ligands. As a rule of thumb, bivalent ligands with a spacer of optimal length are envisaged to exhibit a potency that is greater than that derived from the sum of its two monovalent pharmacophores. They may allow targeting certain dimeric receptors, thereby increasing the selectivity of drug action. The design of such molecules requires the choice of appropriate pharmacophores, the selection of suitable attachment points for the spacer - and the length and chemical structure of the spacer. We also illustrated how a bivalent ligand bridges the GPCR dimer in vitro and in vivo by numerous recent studies.

The main objectives of this thesis are described in Chapter II.

Heterobivalent ligands have been proven useful molecular probes for confirming and targeting heteromeric receptors. Chapter III describes the design and synthesis of novel heterobivalent ligands for the dopamine D₂-like receptors (D₂-likeR) and the μ opioid receptor (μ OR) and their biological evaluation using ligand binding and functional assays. To assess their functionality, D₂-likeR induced MAPK phosphorylation was quantified in the presence or absence of bivalent ligands. Furthermore, β -arrestin2 recruitment was studied via NanoBiT to evaluate stimulation of the μ OR.

In Chapter IV we designed and synthesized a series of bivalent D₂R ligands and mGluR5 allosteric antagonists pharmacophores linked through spacers of varying length as tools to study the functional interaction between D₂-likeR and mGluR5. Ligand binding allowed to determine the affinity of the bivalent ligands for both protomers. In addition, cAMP and MAPK phosphorylation assay was utilized to assess the signal transduction for both receptors.

Chapter V describes the synthesis of fluorescently labeled ligands as potential pharmacological tools to study receptor localization, trafficking, and signaling processes via fluorescence imaging. They could also be employed in fluorescent binding assays to study ligand/receptor interactions. The BODIPY labeled mGluR5 fluorescent ligands were applied to investigate ligand-receptor interactions via a NanoBRET.

A general conclusion of this PhD work is given in Chapter VI.

Finally, Chapter VII is dedicated to the discussion of the broader international context of small-molecule drugs targeting GPCRs, relevance of recently reported bivalent GPCR ligands, as well as future perspectives regarding the design and evaluation of bivalent ligands.

Samenvatting

In veel ziekteprocessen worden G-proteïne gekoppelde receptoren (GPCRs) over- of onder gestimuleerd. Dit verklaart waarom de farmaceutische industrie (stimulerende of blokkerende) drugs heeft ontwikkeld om deze over- of onder stimulatie te normaliseren. Ongeveer de helft van de klinische drugs die tegenwoordig worden gebruikt, interfereren met de werking van deze GPCRs.

Hoofdstuk 1 biedt de algemene introductie van GPCRs, zoals de structuur van GPCRs, classificatie, signalisatie, alsook de GPCR dimerisatie. Verder wordt er in dit hoofdstuk ook een beperkt overzicht gegeven van bivalente liganden die GPCR-dimeren als doelwit hebben. In dit overzicht, wordt de nadruk hoofdzakelijk gelegd op de recente studies over deze bivalente liganden. Indien bivalente liganden zijn uitgerust met een linker van optimale lengte, kan een grotere potentie worden verkregen, in vergelijking met de potentie afkomstig van de som van de twee monovalente farmacoforen. Dit kan ervoor zorgen dat er preferentieel kan worden geïnterageerd met bepaalde dimerische subtypes, wat de selectiviteit van de drugs doet stijgen. De ontwikkeling van zo'n molecule vereist de keuze van farmacoforen, de aanhechtingpunten van de linkers op de farmacofoor en de lengte en de chemische structuur van de linker. We tonen ook met meerdere recente studies aan hoe bivalente liganden binden met de GPCR-dimeren.

Hoofdstuk II beschrijft de kerndoelstellingen van dit proefschrift.

Het is reeds bewezen dat heterobivalente liganden zeer nuttige moleculen zijn voor de bevestiging van het bestaan van, alsook het *targeten* van heteromere receptoren. Hoofdstuk III beschrijft de ontwikkeling en de synthese van nieuwe heterobivalente liganden voor de dopamine D₂-like receptoren (D₂-likeR) en de μ -opiaatreceptor (μ OR) en hun biologische evaluatie, op basis van radioactieve ligandbindingstechnieken en functioneel onderzoek. Voor dit laatstgenoemde werd de MAPK fosforylatietechniek geïmplementeerd om de D₂-likeR te testen in de aan- of afwezigheid van bivalente liganden. Verder werd de β -arre2 recrutering via de NanoBiT techniek toegepast om de signalisatietransductie van μ OR te analyseren.

Hoofdstuk IV beschrijft het ontwerp en de synthese van een aantal bivalente liganden waarbij D₂-likeR agonist en mGluR5 antagonist farmacoforen, aan elkaar zijn gehecht met linkers van variërende lengte. Deze dimeren worden vervolgens gebruikt als *tools* om de functionele interactie tussen de D₂-likeR en mGluR5 te onderzoeken. Ligandbindingsexperimenten stelden ons in staat om de affiniteit van de dimere liganden voor beide promotoren te bepalen. Daarnaast werd een cAMP en MAPK fosforylatieassay gebruikt om de signaaltransductie voor beide receptoren te bestuderen.

Hoofdstuk V beschrijft de ontwikkeling van fluorescent gelabelde liganden als farmaceutische gereedschappen om receptorlokalisatie, -transport en -signalisatie te bestuderen via fluorescente beeldvormingstechnieken. Deze liganden worden ook toegepast bij fluorescente bindingstechnieken om ligand/receptor interacties te kunnen bestuderen. Er werd gebruik gemaakt van mGluR5 liganden gelabeld met BODIPY fluoroforen om de ligand-receptor interacties te onderzoeken via NanoBRET.

Het algemeen besluit van deze PhD thesis staat beschreven in hoofdstuk VI.

Hoofdstuk VII omvat de discussie van de brede context van *small-molecule* drugs die GPCRs als doelwit hebben, de relevantie van recent gerapporteerde bivalente GPCR-liganden, alsook de toekomstige perspectieven omtrent het ontwerp en de evaluatie van bivalente liganden.

t	Triplet
TBAF	Tetra-n-butylammonium fluoride
TBTA	Tris[(1-benzyl-1H-1,2,3-triazol-4-yl)methyl]amine
TFA	Trifluoroacetic acid
THF	Tetrahydrofuran
TLC	Thin-layer chromatography
TR-FRET	Time-resolved fluorescence resonance energy transfer
UV	Ultraviolet
v	Volume
YFP	Yellow fluorescent protein

CHAPTER I

INTRODUCTION

I. INTRODUCTION

I.1. General introduction of GPCR

Our body is composed of cells that need to communicate with each other for proper functioning. Towards this end cells contain many different receptors, involved in passing information from outside the cell to the intercellular environment and to control physiological processes (e.g. food digestion, muscle contraction, mood, etc.). By means of messengers (e.g. neurotransmitters or hormones), G protein-coupled receptors (GPCRs) represent the largest group of cell membrane receptors. In many disease processes GPCRs are over- or understimulated, explaining why the pharmaceutical industry develops drugs (blockers or stimulators) to compensate for this over- or understimulation. Almost half of today's clinically used drugs act directly or indirectly on GPCRs.

I.1.1 Structure of GPCR

G protein-coupled receptors (GPCRs), which are also known as 7-transmembrane receptors, heptahelical receptors or serpentine receptors, constitute the largest protein family of cell surface receptors encoded by the human genome. Structurally, GPCRs consist of seven-transmembrane α -helices (7-TM) connected by three extracellular loops and three intracellular loops, with an extracellular N-terminal region and an intracellular C-terminus at each end of the 7-TM domain. GPCRs can recognize extremely diverse stimuli, including neurotransmitters, hormones, growth factors, chemokines and light, to receive messengers from outside the cell and transfer these into the activating internal signal transduction pathways and, ultimately, cellular responses.[1]

Figure 1. Schematic representation of a class A GPCR

All GPCRs consist of seven hydrophobic transmembrane domains separated by three intracellular (IC) and three extracellular (EC) loops. The N-terminus is exposed to the extracellular environment and often possesses N-glycosylation site(s). The C-terminal tail is located intracellularly.

GPCRs participate in a diversity of important physiological functions and are the targets of a large number of therapeutic agents.[2]

I.1.2 Classification of GPCR

Over the past decade, Fredriksson et al. performed large scale phylogenetic analyses of over 800 GPCRs in the human genome and divided these into five families on the basis of phylogenetic criteria. They proposed the GRAFS system to classify five main families termed Glutamate (G), Rhodopsin (R), Adhesion (A), Frizzled/Taste2 (F) and Secretin (S).[3] In the more classical A-F system, GPCRs are divided into six subfamilies based on sequence homology and functional similarity: rhodopsin-like (class A), secretin-like (class B), metabotropic glutamate (class C), fungal pheromone receptors (class D), cyclic AMP receptors (class E) and frizzled/taste2 (class F).[4]

The largest class A GPCR family (A-F system) contains more than 700 members that recognize particularly diverse ligands including inorganic ions, organic odorants, peptides, biogenic amines, lipids, proteins, nucleotides, and photons (rhodopsin, the first GPCR of which the structure was resolved).[5] These ligands can initiate downstream signals through either G protein or β -arrestin pathways. This family comprises very extensively studied GPCRs like adrenoceptors, chemokine receptors, adenosine receptors, opioid receptors and dopamine receptors. Class B GPCR members mostly bind large peptides and their N-terminus plays a key role in binding the ligand. Family C GPCRs are characterized by a long N-terminus, which plays a vital role in ligand recognition. The three other families are less studied.

I.1.3 GPCR signaling

I.1.3.1 G protein-dependent signaling

It is well known that G proteins are composed of α , β , and γ subunits, which are associated in an inactive state. The heterotrimeric G proteins are key in GPCR signaling.[6] Figure 2 shows the regulatory cycle of G proteins, i.e. activation/inactivation through GPCR ligand binding. In the inactive state, the $G\alpha$ subunit is bound to a $G\beta\gamma$ dimer and GDP. G protein-dependent signaling starts by binding of an agonist that activates the GPCR. As a result of conformational changes, the activated GPCR catalyzes the exchange of GTP for GDP on the $G\alpha$ subunit, which leads to the dissociation of the $G\beta\gamma$ dimer from $G\alpha$. Activated $G\alpha$ and $G\beta\gamma$ proteins in turn bind to and modulate various effectors, which will influence the intracellular concentration of different second messengers. Finally, the intrinsic GTPase activity of $G\alpha$ comes into play, which leads to the hydrolysis of bound GTP into GDP and hence the inactivation of G proteins cascade. GTPase activity of the $G\alpha$ subunits may also be regulated by regulators of G proteins signaling (RGS proteins) as well as effectors.

The activated $G\alpha$ subunit interacts and positively regulates numerous effectors such as potassium and calcium channels, phospholipase C (PLC), protein kinases and adenylyl cyclase (AC), which upon activation catalyzes the conversion of ATP into cAMP, a second messenger important in many biological processes.[7] It was discovered that the $\beta\gamma$ subunits could also activate the muscarinic K^+ channel and positively regulate many effectors including AC, phospholipase C- β (PLC- β), phospholipase A_2 (PLA $_2$), phosphoinositide 3-kinase (PI3-kinase) and β -adrenergic receptor kinase.[8] Furthermore, $G\beta\gamma$ can activate $G\alpha$ subunit. [9] It is now clear that many effectors are regulated by both α and $\beta\gamma$ subunits.

Figure 2. G protein-dependent signaling

In its inactive state the subunits of heterotrimeric G proteins ($G\alpha$ and $G\beta\gamma$) are associated and GDP is bound to $G\alpha$ ($G\alpha$ -GDP). Upon agonist binding, GPCRs undergo conformational changes, which lead to dissociation of $G\alpha$ from $G\beta\gamma$ subunit. In the active state GTP is bound to $G\alpha$ ($G\alpha$ -GTP). Now free $G\alpha$ and $G\beta\gamma$ have their own effectors to further transmit the signals and initiate unique intracellular signaling responses. Signal transduction ceases due to the intrinsic $G\alpha$ -GTPase activity, which hydrolyzes the bound GTP ($G\alpha$ -GTP) to GDP and P_i and inactivates the G protein complex by re-associating the $G\alpha$ with $G\beta\gamma$.

I.1.3.2 G protein-independent signaling

GPCRs may transduce their signals through G protein-independent mechanisms, and heterotrimeric G proteins may also play functional roles in non-GPCR signaling. β -arrestins are multifunctional proteins, which are very important regulators of GPCR function. There are two forms of β -arrestin, β -arrestin1 and β -arrestin2 (also known as arrestin2 and arrestin3, respectively). Most studies have focused on the consequences of β -arrestin2 recruitment. Specifically, β -arrestins are required for the termination of G protein signaling and the initiation of arrestin-mediated signal transduction by GPCRs. The termination of G protein signaling is promoted by phosphorylation of the intracellular loops of the activated GPCR via a G protein kinase (GRK). GPCR phosphorylation is involved in the recruitment and activation of β -arrestin, which triggers receptor internalization and sometimes initiation of the arrestin-mediated signaling cascade.[10]

β -arrestins can recruit catalytically active proteins to the activated receptors, amongst which p44/p42 mitogen-activated protein kinases (MAPK) are the most important ones.[11],[12] Some studies have focused on the significance of β -arrestins in the regulation of p44/42 MAPK phosphorylation.[11] β -arrestin-dependent and G protein-dependent phosphorylation of MAPK was shown for different GPCRs, among others angiotensin II type 1 receptors (AT_1Rs),[13],[14] neurokinin 1 receptor (NK_1)[15], parathyroid hormone receptor (PTHrP)[16], vasopressin V_2 receptor (V_2R)[17], and β_2 -adrenergic receptor (β_2AR)[18]. Studies involving AT_1Rs , PTHrP and β_2AR suggest a common β -arrestin-mediated MAPK activation that exhibits different kinetics compared to G protein-mediated MAPK signaling. G protein-dependent MAPK activation occurs very rapid and transient, while β -arrestin-dependent MAPK activation is slower and more sustained.[16],[19],[20]

Figure 3. The G protein- and β -arrestin-mediated signaling

Activation of a GPCR can initiate two independent signaling pathways: 1) classical GPCR signaling pathway via heterotrimeric G proteins leads to the activation of membrane-delimited effectors like AC, phospholipase C isoforms (PLC), MAPK and ion channels that generate intracellular second messengers; 2) in the G protein-independent pathway β -arrestins (depicted in orange) can serve as scaffolds linking GPCRs to non-traditional effector pathways like non-receptor tyrosine kinases (TK), MAPK, and E3 ubiquitin ligases. β -arrestins can also inhibit G protein-coupling to the receptor, which makes the two pathways mutually exclusive.[91]

I.1.4 GPCR dimerization

For a long time, GPCRs have been considered to exist and function as monomers within the plasma membrane. However, in the past decades an increasing number of studies revealed that GPCRs are capable of forming dimers or even higher-ordered oligomers, which may modulate receptor function.[21],[22],[23]

The first hypothesis on GPCR heteromers was already raised in the early eighties after observations of neuropeptide-monoamine receptor-receptor interactions.[24],[25] The existence of heteromers was confirmed almost twenty years later for two non-functional GPCR monomers, i.e. the gamma amino butyric acid (GABA) receptors, GABA-B1 and GABA-B2, which assemble at the cell surface in a signaling heterodimer, the GABA-B receptor.[26] Now, dimerization has been described for many GPCRs in *in vitro* settings although evidence in native tissue is still sparse.[27],[28]

Both homodimers and heterodimers may exhibit properties distinct from those of the constituting protomers including distinct ligand binding properties, altered signaling and trafficking properties.[90] GPCR dimerization can result in altered binding properties that are not compatible with the model that one single GPCR binds one ligand. Studies on signaling assays such as receptor-mediated G-protein activity, adenylyl cyclase activity, MAPK phosphorylation, and β -arrestin-mediated signaling have

provided evidence that dimerization can change signal transduction.[22] Moreover, dimerization plays an essential role in the regulation of receptor processing and trafficking, including receptor maturation, cell surface delivery, and ligand-mediated endocytosis.[21],[22]

I.1.5 Techniques used to study GPCR dimerization

Many techniques have been utilized to detect the GPCR dimers in living cells and tissues. Here we summarize some typical physicochemical (Coimmunoprecipitation, Co-IP), fluorescence-based (FRET, TR-FRET, BRET and PLA), and complementation-based techniques such as NanoBiT. Bivalent ligands that also have been frequently used as pharmaceutical tools to study GPCR dimerization will be discussed later.

I.1.5.1 Co-immunoprecipitation (Co-IP)

To investigate direct physicochemical interaction between two GPCRs, co-immunoprecipitation (co-IP) of differentially epitope-tagged receptors is one of the most broadly used techniques.[29] If suitable antibodies against the endogenous receptors are available, these can be used to immunoprecipitate endogenous receptors. Because it is often very difficult to find a good antibody against an endogenous receptor, this approach often uses differentially epitope-tagged (such as cMyc-, HA-, His-, or FLAG-tagged) receptors, which are co-expressed in heterologous cells, together with two specific antibodies. The potentially formed dimers are immunoprecipitated by a specific antibody against one epitope, followed by immunoblotting using a specific antibody against the other protomer. Typically, Co-IP is performed with total cell lysates, but when studying membrane proteins, modification of this technique is recommended. The principle of co-IP is described in Figure 4. Although co-IP reveals the presence of both receptors in the same complex, it does not provide evidence of physical interaction between the protomers. Therefore, co-IP is often complemented with fluorescence-based methodology to validate the obtained results.

Figure 4. Schematic summary of a standard co-immunoprecipitation assay. (Adapted from Thermo Fisher SCIENTIFIC)

A coupled antibody against a specific antigen conjugating a protein of interest forms an immune complex. Then the immune complex is captured, or precipitated on a beaded support. Next an antibody-bound protein is immobilized, and proteins not captured or precipitated on the beads will be washed away. In the end, the antigen (and antibody, if it is not covalently conjugated to the beads or when using buffers for denaturing) is eluted from the support.

I.1.5.2 FRET

Fluorescence resonance energy transfer (FRET) is based on energy transfer between donor and acceptor molecules in close proximity (Figure 5).[30] A distance smaller than 10 nm and an overlapping absorption spectrum of the acceptor with the emission spectrum of the donor are essential for efficient energy transfer. By exploitation of FRET, energy transfer-competent pairs of fluorescent proteins have been attached to the C-terminus of the GPCR (such as cyan fluorescent protein (CFP) as donor and yellow fluorescent protein (YFP) as acceptor). Background fluorescence from sample components like buffers, proteins, chemicals and cell lysate may hamper traditional FRET. Such background fluorescence is very transient (with a nanosecond range of lifetime) and can therefore be reduced by using time-resolved fluorescence resonance energy transfer (tr-FRET) as shown in Figure 6a.

Figure 5. Schematic representation of the interaction of two different fluorescent proteins. Protein-protein interactions between GPCRs labeled fluorescent proteins bring cyan fluorescent protein and yellow fluorescent proteins in close enough proximity to allow for FRET to occur.

I.1.5.3 Ligand-tr-FRET

Ligand-tr-FRET makes use of fluorescently labeled ligands instead of labeled proteins. One ligand is coupled to an acceptor fluorophore, while the other ligand is coupled to a donor, causing energy transfer if both receptors are in close proximity.[31] The required ligand-fluorophore conjugates may be accessible from synthetic intermediates used for the construction of the heterobivalent ligands. (Ligand-)TR-FRET assays are sensitive, can be miniaturized and display reduced autofluorescence, but there is a limited choice of donor/acceptor pairs. Moreover, it might be challenging to label donor and/or acceptor/ligands without interfering with receptor binding affinity.

Figure 6. Fluorescence-based techniques.[92] a) tr-FRET strategies use lanthanide-labeled antibodies against N-terminal-tagged GPCRs to monitor receptor dimerization at the cell surface, which is based on the energy transfer between a lanthanide (e.g. Europium³⁺, Eu³⁺) and a compatible fluorophore (e.g. allophycocyanin, APC). Because of the long-lasting light emission of the lanthanides, tr-FRET provides a significantly improved signal-to-noise ratio. b) Ligand-tr-FRET uses fluorescently labeled ligands instead of labeled proteins.

I.1.5.4 BRET

The luminescent variant of FRET where energy transfer occurs between a luminescent donor and a fluorescent acceptor is called bioluminescence resonance energy transfer (BRET, Figure 7). The enzymatic oxidation of a substrate leads to the emission of energy from the donor, which means that no excitation light is needed in contrast to FRET. Moreover, the enzyme reaction does not produce a background signal and the assay is therefore more sensitive than FRET.[32] Taking advantage of BRET, a bioluminescent protein, commonly luciferase from *Renilla reniformis* (Rluc), has been used as an energy donor and a fluorescent protein (YFP, GFP2, or mOrange) as an acceptor.[33] Because of the fact that there is no requirement of a light source, the instrumentation for BRET[34] makes these assays applicable for high-throughput screening. Nevertheless, because of the large fluorescent and bioluminescent probes, it is necessary to consider which label to choose, how to label the ligand and/or receptor (with or without spacer), and to assess the effect of labeling on the binding properties.

Figure 7. Schematic representation of BRET. Protein-protein interactions between GPCRs labeled with a luminescent donor and a fluorescent acceptor bring Rluc and YFP in close enough proximity to allow for BRET to occur.

I.1.5.5 Proximity ligation assay (PLA)

For in situ detection of heteromers PLA (Olink Bioscience) is a new technique, which has been optimized for brain tissue by the group of Javitch [35]. This technique is based on immunolabeling with two primary antibodies from different species and then with different species-specific secondary antibodies. The two secondary antibodies, each recognizing a specific species, are covalently coupled to oligonucleotides, the so-called proximity MINUS and PLUS probes. When both secondary antibodies are near to each other proximity-dependent ligation and rolling circle amplification of a circular DNA reporter molecule occurs, which can be visualized.[36]

Figure 8. Principle of Proximity Ligation Assay. (Adapted from Abnova)

I.1.5.6 NanoLuc Binary Technology (NanoBiT)

A new complementation-based approach termed NanoLuc binary technology (NanoBiT) was used to study protein-protein interactions in living cells.[37] It utilizes inactive subunits of NanoLuc luciferase, Large BiT (LgBiT; 18 kDa) and Small BiT (SmBiT; 1 kDa), which are coupled to two proteins of interest. Protein interaction promotes structural complementation of the subunits, thus restoring NanoLuc luciferase activity, which generates a bioluminescent signal in the presence of the furimazine substrate.

An optimized assay was established to be capable of detecting the dimerization of GPCRs (e.g. D₂R).[38] Candidate GPCRs are fused to SmBiT or LgBiT. Upon GPCR dimerization, the NanoBiT fragments come into close proximity resulting in NanoLuciferase reconstitution, which can convert the furimazine substrate leading to the emission of light.

Figure 9. Schematic representation of the NanoBiT system.[38]

Table 1 summarizes studies on GPCR dimerization containing at least one of the dopamine receptors, opioid receptors and metabotropic glutamate receptors.

I.2. Bivalent ligands of G protein-coupled receptors (GPCRs)

In classical pharmacology allosteric mechanisms were only discussed in terms of intramolecular interactions within a receptor between orthosteric and allosteric sites. Nowadays, there is mounting evidence that also intermolecular receptor-receptor interactions may result in altered receptor recognition, pharmacology and signaling. Bivalent ligands[93],[94],[95] have been proven useful molecular probes for confirming and targeting dimeric receptors, such as the κ opioid receptor (κ OR)- δ OR heteromers.[93] Bivalent ligands are valuable tools to demonstrate the existence of receptor dimers even in native tissue and can be used to study a specific GPCR dimer behavior without any receptor modification.[96],[97],[98] Such compounds may also evolve to useful pharmacological agents.[97]

Bivalent ligands with a spacer of optimal length are anticipated to exhibit a potency that is different from that derived from its two monovalent pharmacophores and may allow the targeting of certain dimeric subtypes, thereby increasing the selectivity of drug action.[98],[99],[100] Such synergy is based on the assumption that a bivalent ligand will first undergo univalent binding, followed by binding of the second pharmacophore to a recognition site on a neighboring receptor (Figure 10). When the bivalent ligand is in the univalently bound state, the pathway to bivalent binding should be favored over univalent binding of a second ligand because of the small containment volume of the tethered, unbound pharmacophore that is in the region of the unoccupied neighboring receptor site. The situation may be different in case the neighboring receptors are negatively allosterically coupled. In that case the binding enhancement may be mitigated.

Figure 10. Bivalent ligand concept for bridging a receptor dimer.

The unoccupied dimer (A) undergoes univalent binding that leads to state B. The unoccupied site in B can be “bridged” to give D, which is entropically favored over binding of a second ligand to give the dimer with both sites occupied (C).

I.2.1 Concept and design of bivalent GPCR ligands

A typical bivalent GPCR ligand consists of three different components including two pharmacophores, two linking groups and a spacer of optimal length and nature (Figure 11). Specifically, the two pharmacophores are based on GPCR ligands, which could be the same (homo-bivalent ligands) or different (hetero-bivalent ligands). The selected GPCR ligands should be functionalized with a group, e.g. amine, carboxylic acid, alkyne or azide, to allow swift conjugation to the spacer. In addition, the spacer should also be equipped with appropriate ligation handles to couple with GPCR ligands. Overall, the design of such molecules requires the selection of the pharmacophores and attachment points, as well as the selection of appropriate length and chemical nature.

Figure 11. General Structure of Bivalent GPCR Ligands

I.2.2 Functionalized pharmacophore, attachment point and linking groups

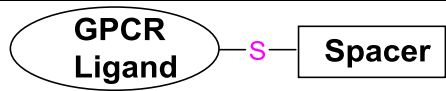

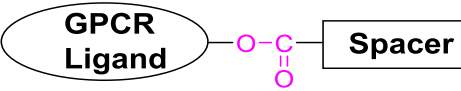

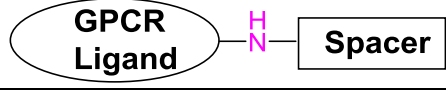

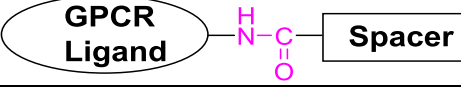

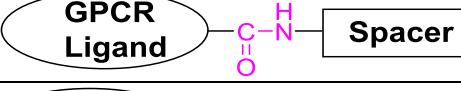

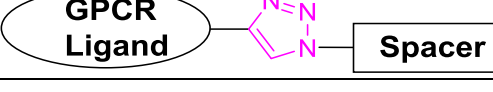

Bivalent ligands represent very promising tools for the study of GPCR dimerization. Aspects such as pharmacophore identification, linker attachment site, length and composition of linker will be addressed in the following part.

The selection of the position and nature of the attachment points for linking the two pharmacophore units to the spacer depends on two criteria: the feasibility of the chemical modification and the compatibility of these modifications with receptor binding and intrinsic activity of the pharmacophore.

Preferred reactive groups (Table 2) for connecting two pharmacophoric units and spacers are hydroxyl, amine, and carboxylic groups,[101],[102] but also alkynes or azides may be employed to generate 1,4-substituted 1,2,3-triazole linking groups via a copper-catalyzed azide–alkyne cycloaddition (CuAAC) reaction.[103],[104],[105] The use of azides and terminal alkynes requires additional reaction steps, as these functional groups are usually not present in most pharmacophores. These functional moieties may be connected to the spacer via ether, amide and triazole moieties. In some studies, ester, amine or thioether functions are also described.

Normally, pharmacophores including the examples shown in Table 3 possess more than one functional group and the spacer has to be attached ideally without significantly disrupting the binding affinity or functionality of the parent compounds. Therefore, the most suitable spacer attachment position is preferentially chosen based on structure-activity relationship (SAR) data. For instance, the phenolic hydroxyl group of morphinans (Table 3), which is known to function as a hydrogen bond donor and to be crucial for appropriate receptor binding of these opioid receptor (OR) ligands, is excluded as a linker attachment point despite its reactive properties. Alternatively, the ketone portion of these OR ligands was chosen as the attachment point (Table 3), after conversion into an amine for connection to the spacer portions via an amide bond.[115]

I.2.3 Spacer Length.

Both the length and composition of the spacer unit are critical for binding of bivalent ligands to their target receptors. Most successful studies on bivalent ligands revealed an impact of the spacer length on

the binding affinity and functional activity, often leading to an optimal spacer length connecting the two pharmacophores.

In an early study of bivalent ligands targeting opioid receptors (μ , δ and κ dimers), Portoghese et al. showed that an optimal distance between the pharmacophores to bridge the GPCR dimer is 18 atoms (~ 20 Å).[36] A recently reported X-ray crystal structure of the μ opioid receptor reveals an optimal spacer length between 18 and 22 atoms to bridge the protomers.[129]

In recent studies, Portoghese and co-workers designed a number of heterobivalent ligands based on opioid receptors ligands.[115],[121] All these that show high potency compared to the monovalent ligands feature optimal spacer lengths of 18 to 22 atoms. The most convincing support for this 18–22 atom spacer requirement for bridging the μ OR and CCK2 dimer employed BRET technology.[115] The data revealed that bivalent ligands **1.01a-c** (Figure 12) containing μ OR agonist and CCK2 antagonist pharmacophores linked through 18–22 atom spacers efficiently induced physical association of coexpressed μ OR and CCK2 receptors by shifting the equilibrium from homodimers to a heterodimer, whereas bivalent ligands with shorter spacers and monomeric ligands were not effective. While clearly established for these studies, the proper spacer length of other dimer spanning bivalent ligands relies on the dimer interface, which often remains ill defined, the structure of the pharmacophores, and the topicity of the attachment points.[130]

Figure 12. Bivalent ligands targeting μ OR and CCK2 receptors with spacer length between 16 and 22 atoms.[115]

Recently, the optimal attachment point for the synthesis of clozapine homobivalent ligands was identified as the N4' position, which also incorporated a linking group between the nitrogen and the spacer.[120] Both functional and binding assays pointed toward a spacer length dependent effect, with the most active compounds (**1.02a** and **1.02b**) having total spacer lengths of 16 and 18 atoms, respectively. These compounds exhibited exceptional high binding affinity (K_i 1.41 and 1.35 nM) and remarkable functional activity (IC_{50} 23 and 44 nM) compared to the original pharmacophore, clozapine, i.e. 75-79-fold increase in affinity and 5-9-fold increase in potency. These clozapine propylamine bivalent ligands were used as pharmacological tools to investigate dopamine D_2R dimerization.

Figure 13. Bivalent ligands of clozapine at the N4' position with optimal spacer lengths of 16 and 18 atoms.

A series of bivalent ligands was synthesized to target cannabinoid 1 (CB1) receptor dimers using two rimonabant (SR141716) pharmacophores connected by different linkers.[126] The potent and selective CB1 receptor antagonist was linked by alkylamine spacers of various lengths, and the resulting bivalent ligands were assessed in radioligand binding and functional assays. These ligands displayed a binding affinity that was spacer length dependent (Figure 15). Bivalent ligand **1.03** ($n = 7$, Figure 14) composed of a 15-atom spacer exhibited the highest gain in affinity as compared to the corresponding monovalent ligand. Thus, this novel compound may serve as a probe that enables further characterization of CB1 receptor dimerization and oligomerization.

Figure 14. Structure of homobivalent CB1R ligands from Zhang et al. [126] Spacer length calculated as $2n+1$. Highest CB1R affinity with $n=7$ (15-atom): R=H (secondary amine): K_i ($hCB1R$)=12.3 nM; R=Me (tertiary amine): K_i ($hCB1R$)=17.3 nM.

Figure 15. Correlation of spacer length and affinity at *hCB1R* for homobivalent *CB1R* ligands. Structures are shown above; K_i values are from Zhang et al.[126] The graphs are from Nimczick et al.[131]

In another recent example, Tanaka et al.[132] employed poly(L-prolines) as rigid spacers in the development of bivalent ligands targeting the CXCR4 chemokine receptor 4 (CXCR4) homodimer. In this case, the bivalent ligand could be used as a “molecular ruler” approach to further understand the details of CXCR4 oligomer formation. Interestingly, more rigid linkers having an optimal length of approximately 6 nm were favored and displayed low nanomolar potency (Figure 16).

Figure 16. Oligoproline helices as molecular rulers. Graphic adapted from Tanaka et al.[132] showing the relationship between binding affinity of bivalent ligands targeting CXCR4 and the length of the spacer conjugating the two pharmacophores.

For their study on D₂R agonist/A_{2A}R antagonist bivalent ligands, Soriano et al. [133] reported a minimum spacer length of 26 atoms, which could increase up to 118 atoms. No correlation was observed between spacer length and binding affinity of the bivalent ligands, which, however, exhibited a significant gain in affinity compared to their monovalent ligands. The bivalent ligands exhibited a Lys-(PEG/polyamide)_n-Lys-Glu spacer unit to span the vast distance between the dimeric binding sites (Figure 17). The advantage of this approach is the extreme length that can be obtained through multiple coupling steps. A disadvantage is the inability to extend the spacer groups incrementally to enable a methodical analysis of the exact distance between the binding sites of the dimer. Although this series of compounds are the first reported bivalent ligands targeting the D₂R/A_{2A}R heterodimer, further optimization of the spacer is required to detect an optimal increase in binding affinity.

Figure 17. Bivalent D₂R/A_{2A}R ligands with spacer lengths ranging from 26–118 atoms between the two pharmacophores.[133]

The above examples demonstrate that there are general no rules governing the optimal spacer distances to construct bivalent ligands for various dimeric GPCRs. However, several criteria on spacer length should be carefully considered to determine the optimal length of the connecting entity in a bivalent ligand: the binding mode of the chosen pharmacophore, the respective relative position of the two linker attachment points and the interface between the two protomers. Overall, in the absence of structural information of the targeted dimer, the optimal length of the spacer in a bivalent ligand may vary and needs to be determined empirically for each new pair of target receptors.

I.2.4 Conformational flexibility and hydrophilicity of the Spacer

In addition to spacer length, the chemical composition of the spacer may play an important role on the binding properties of the prospective bivalent ligands.

Generally, the spacer needs to be flexible enough to allow correct accommodation of each pharmacophore in the binding pocket of each protomer. Portoghese et al. investigated the effect of

conformational rigidity of the spacer on opioid receptor activity. The conformational flexibility of the spacer was reduced by replacement of a succinyl group by a fumaryl moiety. Bivalent ligands containing two β -naltrexamine pharmacophores connected by a succinyl (**1.07a**, **1.07b**, Figure 18)[134] or fumaryl amide (**1.08a**, **1.08b**)[134] revealed significant differences in receptor selectivity. Bivalent ligand **1.07a** bearing the succinyl group was a potent and selective κ OR antagonist, whereas the corresponding fumaryl analogue **1.08a** displayed no κ -antagonistic activity. Interestingly, a recovery of κ antagonism was observed upon increasing the conformational flexibility by introduction of an additional four glycine units (**1.07b** and **1.08b**).

Figure 18. Bivalent naltrexamine ligands featuring succinyl or fumaryl groups in their spacers.[134]

Bivalent D_2 -like receptor ligands (Figure 19) were synthesized using relatively rigid bismethyl-p-biphenyl spacers directly linked by 1,2,3-triazoles to 1,4-DAP pharmacophores. The para-substituted benzamides **1.09** [103] displayed poor binding affinities with K_i values between 70 and 2000 nM at the D_2 -like subtypes. Interestingly, the ferrocenebenzamide **1.10** [103] displayed high binding affinities (K_i of 15, 14, 1.1, and 22 nM for D_{2long} , D_{2short} , D_3 , and D_4 , respectively), which were even surpassing that of bivalent ligand **1.11** with a more flexible methylene spacer.[122] These results clearly demonstrate the importance of conformational flexibility on the binding affinity of dimeric ligands. This study suggests that 1,1'-disubstituted ferrocenyl subunits may be used as molecular hinges when rotation of the cyclopentadienyl moieties enables the two pharmacophores to adopt an optimal orientation.[103]

Figure 19. Ferrocene as a molecular hinge in bivalent D₂-likeR ligands.

A variety of spacer groups were used to synthesize 5-HT₄ receptor bivalent ligands based on the highly potent and specific partial agonist ML10302 (Table 3), including polyalkyl chains, polyethylene glycol (PEG) units, polyamide chains, hydrophobic spacers, cyclic core alkyl spacers, flexible aromatic containing spacers, and constrained aromatic containing spacers (Figure 20). [135] Binding studies indicated that the optimal spacer length was 20–24 atoms for bivalent binding.[136] The rigidity of the spacer, represented in Figure 20 as number of rotatable bonds, is also of considerable interest as it can result in an 'all or nothing' approach as described by Bobrovnik,[137] whereby the appropriately designed rigid spacer can selectively increase the concentration of the pharmacophore to the active site of the binding pocket. Bonger et al.[138] successfully generated bivalent ligands targeting the gonadotropin releasing hormone receptor (GnRHR) with rigid benzene-based scaffolds (Figure 20).[139]

Figure 20. Bivalent 5-HT4 or GnRHR ligands with various spacers.

The above spacers could potentially be incorporated into any bivalent ligand. However, they all have their respective advantages and disadvantages. They mainly differ in lipophilicity and flexibility (number of rotatable bonds).

The polarity of the spacer unit contributes to the overall solubility of the bivalent ligand, which may be relevant, especially when the pharmacophore is very hydrophobic. Indeed, hydrophilic groups like polyamide or polyethylene glycol (PEG) units present in many spacers enhance aqueous solubility.[134],[141],[142] However, polyamide and polyethylene glycol units do not permit one-atom variations. Therefore, polyamide spacers, most commonly polyglycine units, are usually combined with alkyldiamine or methylenediacyl cores as in bivalent opioid receptor ligand **1.12** to combine high polarity with the possibility of one-atom variation.[143],[144],[145] In addition to hydrophilicity of the spacer, flexibility can also be improved using PEG spacers.

Figure 21. Incorporation of oligoglycine and diamine moieties into the spacer.[121]

Both lipophilicity and rigidity of the spacer are important factors when designing a bivalent ligand, and the linkers listed in Figure 20 can serve as a down list for the synthesis of bivalent ligands. Incorporation of piperazine into the spacer group can improve the hydrophilicity of the bivalent ligand, but is slightly less flexible than a polyalkyl chain and PEG spacer, but slightly more than polyamide chains.

I.2.5 Bivalent ligands may enhance selectivity and binding affinity

Bivalent ligands often possess receptor binding properties that differ substantially from those of the monovalent ligands. Several different mechanisms can contribute to their specific binding properties.[146] For instance, bivalent ligands can bind dimeric receptors on the cell surface. In this case, the cost for the translational entropy is paid with the first receptor–ligand contact and subsequent binding interactions proceed without additional penalties in the translational entropy (Figure 22a). Even in the case of receptors that are not dimeric, bivalent ligands can bind avidly to multiple receptors, a process that is facilitated by the two dimensional diffusion of receptors in the fluid bilayer (Figure 22b). As the result, the bivalent ligands can enhance binding affinity, agonist/antagonist potency and GPCR subtype selectivity.[146]

Figure 22. Mechanisms of bivalent ligand–receptor interactions. (a) Bivalent ligands can bind dimeric receptors by occupying multiple binding sites (chelate effect). (b) Bivalent ligands can cause receptors to cluster on the cell surface.

Andersen et al. has synthesized a series of bivalent serotonin ligands to reveal insight into substrate recognition in the serotonin reuptake transporter (SERT).[147] An optimized bivalent serotonin ligand **1.14** (Figure 23) containing a poly(ethylene glycol) spacer binds SERT with >3,700-fold higher affinity than serotonin (**1.13**), indicating that the human SERT has two distinct substrate binding sites.

Figure 23. Structure of serotonin and the corresponding bivalent nd **1.14** and their affinities for the human SERT.

She et al. synthesized a series of homo- and hetero-bivalent ligands targeting muscarinic acetylcholine receptors M_1R – M_5R . [148] The heterodimeric ligand UR-SK75 (**1.16**, Figure 24) containing a M_R dibenzodiazepinone antagonist and a M_1R/M_4R agonist (xanomeline) showed 20-480-fold selectivity for M_2R over the other four subtypes.

Figure 24. Bivalent ligands **1.15** and **1.16** targeting muscarinic acetylcholine receptor.

To increase the affinity and selectivity for the histamine H_2 receptor (H_2R), Pockes et al. [149] prepared bivalent H_2R alkylguanidine ligand **1.19** (Figure 25) that exhibits significantly higher affinity for hH_2R than for hH_1R , hH_3R , and hH_4R (Table 4). This hH_2R selectivity was much more pronounced than for

the monomeric **1.17**. Furthermore, bivalent ligand **1.19** showed a higher functional activity at guinea pig H₂R (atrium) compared to **1.17** and **1.18** (Table 4).

Figure 25. Structure of bivalent H₂R agonist **1.19**.

Table 4. Binding affinities at the human H_{1,2,3,4}R and agonistic activities at the gpH₂R (atrium)

Compd	K_i (μ M) for hH_{1R}	K_i (μ M) for hH_{2R}	K_i (μ M) for hH_{3R}	K_i (μ M) or hH_{4R}	EC ₅₀ (μ M) at gpH ₂ R (atrium)
1.17	>100	4.07	0.038	0.0074	6.92
1.18	>3.3	0.47	2.04	5.62	0.27
1.19	>3.3	0.047	5.62	10	0.0042

In case bivalent ligands show comparable or decreased binding affinities compared to the monovalent compounds this may be ascribed to suboptimal length or composition of the linker or the inadequate selection of the attachment points.

I.2.6 How to estimate if a bivalent ligand bridges the receptor dimer?

In pharmacology, positive cooperative binding is defined as the enhanced binding of a ligand to a receptor in the presence of another ligand binding to a different binding site of the same receptor. In competitive ligand binding assay, the slope of the binding curve is defined as Hill coefficient or Hill slope (n_H), which is indicative of the degree of cooperativity among multiple ligand binding sites. The Hill equation is commonly expressed as follows:

$$\theta = \frac{[L]^n}{K_d + [L]^n} = \frac{[L]^n}{(K_A)^n + [L]^n} = \frac{1}{\left(\frac{K_A}{[L]}\right)^n + 1}$$

The equation's terms are defined as follows:

θ - Fraction of the ligand-binding sites on the receptor protein which are occupied by the ligand.

[L] - Free (unbound) ligand concentration.

K_d - Apparent dissociation constant derived from the law of mass action (the equilibrium constant for dissociation).

K_A - The ligand concentration producing half occupation (ligand concentration occupying half of the binding sites).

n - The Hill slope.

Competitive binding curves follow the law of mass action. A Hill slope of 1 indicates completely independent binding. A Hill slope greater than 1 indicates positive cooperativity binding, i.e. one ligand facilitates binding of subsequent ligands at other sites on the multimeric receptor complex. A value less than 1 suggests negative cooperativity. Antagonists tend to have Hill slope values close to 1 since they fail to show cooperativity, thereby following the general law of mass action for single site competition. Competition assays between agonists and radiolabeled antagonists are often characterized by shallow curves with Hill slopes between 0.5 and 0.7. [122]

Cross-talk between GPCRs forming a dimer can evoke positive cooperativity, which also can be induced by bivalent ligand owing to the thermodynamic advantage of sequential ligand binding. This effect was observed in the study of bivalent ligands of dopamine D_2 receptor (D_2R) based on 1,4-disubstituted aromatic piperazine (1,4-DAP). Competitive binding curves of monomeric antagonists such as the phenylpiperazine **1.20** [150] (Figure 26) usually show Hill slopes close to 1 ($n_H = 0.9\sim 1.2$), indicating a binding mode whereby one monovalent ligand binds to one receptor protomer. Bivalent D_2R antagonist **1.21a** [150] displayed a remarkably increased Hill slope of 2.0, indicating positive cooperativity. Positive cooperativity is usually observed as an allosteric effect, which induces a conformational crosstalk within one receptor protomer or modulates the interaction between two protomers of a receptor dimer. Bivalent ligands addressing two adjacent binding sites of receptor dimers will also induce such positive cooperativity because bivalent binding of the second pharmacophore is significantly accelerated owing to its vicinity to the second binding site and the enrichment of its local concentration. Therefore, bivalent binding leads to the liberation of 2 equiv of radioligand and a substantial steepening of the competition curve.

Figure 26. Bivalent and monovalent binding mode of **1.20** (**4b**) and **1.21a** (**1b**) at the human dopamine D_{2short} receptor.

Interestingly, bivalent agonists also exhibited steeper binding curves compared to their corresponding monovalent ligands. Monomeric D₂R agonists reveal shallow curves with Hill slopes of 0.5~0.7, suggesting negative cooperativity. While binding studies of bivalent D₂R agonist **1.21b** (Figure 27) revealed significantly increased Hill slopes of 1.3–1.4, indicating positive cooperativity and a bivalent binding mode.[122],[130],[151] Careful analysis of Hill coefficients may thus constitute a valuable approach to confirm a true bivalent binding mode.

Figure 27. Structure of bivalent D₂R ligands.

Meanwhile, the heterobivalent ligands **1.21c** and **1.21d** containing a D₂R agonist (aminoindane pharmacophore) and a D₂R antagonist (phenylpiperazine pharmacophore) were also assessed for their ability to inhibit cAMP accumulation and induce D₂R internalization (Figure 28).[122] The results of cAMP assay revealed that **1.21c** shows weak partial D₂R agonist activity (E_{max} = 13%), whereas **1.21d** exhibited D₂R antagonism. In addition, neither bivalent ligand could activate D₂R-mediated internalization. Therefore, these two heterobivalent ligands do not show D₂R biased agonisms (cAMP versus internalization).

Figure 28. Bivalent D₂R ligands. A cartoon illustrating the effect of bivalent ligands binding to the D₂R dimer on D₂R-mediated cAMP formation and internalization. Red square and blue circle represent D₂R agonist and antagonist pharmacophores, respectively.

Four cartoons further clarified the influence of different bivalent ligands on the signal transduction of D₂R homodimer (Figure 28). Monovalent D₂R agonists binding to the D₂R homodimer could induce cAMP accumulation and activate the D₂R-mediated internalization (Figure 28A), as did the bivalent D₂R agonists (Figure 28B). Bivalent D₂R antagonists binding, on the other hand, blocked both cAMP formation and internalization (Figure 28C). Interestingly, heterobivalent ligands comprising a D₂R agonist and a D₂R antagonist lead to a very low efficacy of cAMP ($E_{\max} \leq 15\%$), indicating partial D₂R agonism, and inhibit D₂R internalization (Figure 28D).

Figure 29. Bivalent ligands (**1.22-1.24**) for D_2R and NTS_1R .

A recent study on bivalent D_2R agonist/antagonist and neurotensin NTS_1 receptor (NTS_1R) agonist ligands (Figure 29) afforded biphasic competition-binding curves when measuring [^3H]spiperone displacement.[153] Such biphasic-binding curves (two K_i values, Figure 30) were specifically observed with spacer lengths of 44 ($m=2$), 66 ($m=3$) or 88 ($m=4$) atoms at cell membranes coexpressing $\text{D}_2\text{R}/\text{NTS}_1\text{R}$. The $K_{i \text{ high}}$ values correspond to a bivalent receptor-bridging binding mode to $\text{D}_2\text{R}/\text{NTS}_1\text{R}$ heterodimers, while the $K_{i \text{ low}}$ values reveal a monovalent-binding mode to D_2R .

Figure 30. Biphasic competition-binding curves indicate a bivalent binding mode of **1.22** (**1b**), **1.23** (**2b**) and **1.24** (**3b**).

Similar binding assays were performed in the presence of an excess of NTS_1R agonist NT(8-13) ($1 \mu\text{M}$), which could prevent a biphasic binding mode of the bivalent compounds by hampering binding of their NT(8-13) pharmacophore to the NTS_1R . Indeed, co-incubation prevented high-affinity binding, resulting in typical sigmoidal monophasic curves (Figure 31a).

To confirm the bivalent receptor-bridging binding mode, reciprocal competition experiments were performed with the NTS₁R radioligand [³H]neurotensin. Employing **1.24**, a biphasic-binding curve was observed with a $K_{i \text{ high}}$ value of 0.11 pM and a $K_{i \text{ low}}$ at 1.7 nM, which was shifted to a monophasic sigmoidal binding curve in the presence of haloperidol (K_i 0.79 nM, Figure 31b). Incubation with this monovalent D₂R antagonist thus efficiently prevented the bivalent-binding mode. Affinities for this competition-enforced monovalent-binding mode were found to be in good agreement with results obtained with membranes from CHO-cells stably expressing NTS₁R only (K_i 0.86 nM). To further complement the results obtained with overexpressing heterologous cell lines with results from native brain tissue, competition binding assays with [³H]spiperone and the bivalent ligand **1.24** were performed with membranes from porcine striatum (Figure 31c). Interestingly, compound **1.24** displayed a biphasic binding curve with a 140-fold preference for the high-affinity binding site over the low-affinity receptor population ($K_{i \text{ high}}$ 2.8 nM, $K_{i \text{ low}}$ 310 nM, high-affinity fraction 38%). In line with the results from heterologous cell lines, addition of 1 μ M NT(8-13) reverted this biphasic binding curve to a sigmoidal binding isotherm with a K_i value of 28 nM. The superior binding of bivalent over monovalent ligands to D₂R/NTS₁R heterodimers was thus not only evident in heterologous cell lines but also in native tissue, though less pronounced, which might be explained by lower receptor expression levels leading to a lower propensity to form D₂R/NTS₁R heterodimers.

Figure 31. Prevention of bivalent binding mode abolishes biphasic competition curves. (a) Dopamine receptor binding of **1.24** (3b, $m=2$, 44-atom spacer) at D₂R/NTS₁R in the absence (blue open circles) or presence (blue inverted triangles) of 1 μ M NT(8-13). Incubation with the monovalent NTS₁R agonist NT(8-13) prevents a bivalent binding mode and converts the biphasic-binding curve into a monophasic sigmoid competition curve. (b) Neurotensin receptor binding of **1.24** at D₂R/NTS₁R in the absence (blue open circles) or presence (blue filled triangles) of 1 μ M haloperidol. Incubation with the monovalent D₂R antagonist prevents the bivalent binding mode, observed for the coexpression of D₂R/NTS₁R. (c) When radioligand displacement studies were performed with striatal membranes and [³H]spiperone, biphasic binding mode was observed for the bivalent ligand **1.24** (blue filled squares) alone, but not in the presence of 1 μ M NT(8-13) (blue open squares).

I.2.7 In vivo relevance of bivalent ligands

Akgün et al. reported a series of bivalent ligands that contain a μ OR agonist and a mGluR5 antagonist pharmacophore linked through spacers of varying length (10–24 atoms) to study the μ OR/mGluR5 receptor interaction in vivo (Figure 32) [118]. Bivalent ligands (intrathecal administration) were evaluated for antinociception using the tail-flick and von Frey assays in mice pretreated with lipopolysaccharide (LPS) or in mice with bone cancer. In LPS-pretreated mice, **1.25** with a 21-atom spacer exhibited the highest potency ($ED_{50} \sim 9$ fmol per mouse), while bivalent ligands with shorter or longer spacers showed at least a 25-fold higher ED_{50} . The exceptional potency of **1.25** may be owing to the optimal bridging of protomers in the target μ OR-mGluR5 heterodimer. Bivalent ligand **1.25** holds a $>10^6$ therapeutic ratio and may be a promising candidate for treatment of chronic, intractable pain via spinal administration.

Figure 32. Bivalent μ OR and mGluR5 ligand.[118]

Portoghese et al.[152] proposed a simple model for the induction of μ OR-mGluR5 heterodimer by **1.25** that could contain the following steps (Figure 33): (a) univalent binding of **1.25** to a mGluR5 (or μ OR) oligomer; (b) dissociation of **1.25**-bound to mGluR5 protomer from the oligomer; (c) association with a μ OR oligomer via assistance of the free μ OR agonist pharmacophore of **1.25**; (d) dissociation of the bridged **1.25**-bound oligomer from the μ OR oligomer to give the **1.25**-bound μ OR/mGluR5 heterodimer

complex. Whereas many other models of induced heterodimer formation are also possible, the crucial feature for all would be the optimal length and nature of spacers incorporated into the bivalent ligand.

Figure 33. Illustration of the concept of μ OR–mGluR5 heterodimer induced by **1.25**. Green square and red circle represent mGluR5 antagonist and μ OR agonist pharmacophores, respectively.[152]

Cross-talk between opioid and chemokine receptors is initiated by chemokine release which, to some extent, leads to reduced potency of morphine in the treatment of chronic pain. Based on the probability that a μ OR–CCR5 heteromer is involved in such cross-talk, Akgün et al.[119] synthesized a series of bivalent ligands that consist of μ OR agonist and CCR5 antagonist pharmacophores linked through homologous spacers (14–24 atoms).

When tested on the lipopolysaccharide (LPS) inflamed mice, the bivalent ligand **1.26** (Figure 34) with a 22-atom spacer displayed excellent antinociceptive activity (i.t. $ED_{50} = 0.0146$ pmol/mouse) that was 2000-fold higher than morphine. Furthermore, **1.26** was approximately 3500-fold more potent than a combination treatment of the corresponding μ OR agonist and CCR5 antagonist. These results clearly indicate that **1.26** bridges the protomers of a μ OR–CCR5 heterodimer, which was supported by docking studies, and that the μ OR–CCR5 heterodimer could act as a novel target for the treatment of chronic pain.

Figure 34. Bivalent ligand **1.26** bridging μ OR and CCR5 receptors.[119]

Based on the above studies on opioid receptor, a main difference between the bivalent ligands and clinically used opioid ligands is their remarkable potency in both reducing hyperalgesia and strengthening antinociception without tolerance in inflamed mice. To further identify the targets of bivalent ligands **1.25** and **1.26**, Akgün et al. has undertaken a study upon i.t. administration recently.[154] The results showed that the high potency of **1.25** and **1.26** in LPS inflamed mice is partially owing to their contributions to directly blocking the activated spinal glia. Specifically, compound **1.25** displayed the potently enhanced antinociception due principally to selective inhibition of activated astrocytes, while **1.26** antinociception was owing mainly to blockage of induced spinal microglia.

Lacking μ OR/ δ OR heterodimer-selective antagonists is the major limitation in the study of μ OR/ δ OR dimerization. Hence, Olson et al. synthesized a series of varying length (15–41 atoms) bivalent peptides with selective but moderate/low-affinity pharmacophores for the μ OR and δ OR (Figure 35).[155] The pharmacological results showed a spacer length dependent μ OR/ δ OR dimer affinity/potency profile in vitro, with the 24-atom spacer length **1.29** (D24M) generating the highest affinity/potency (<1 nM) at the μ OR/ δ OR dimer and selectivity (≥ 89 -fold relative to the μ OR or δ OR monomer). In addition, **1.29** displayed ≥ 200 -fold higher potency than the monomeric compounds at the μ OR/ δ OR heterodimer.

Subsequently, **1.29** was further evaluated in the tail flick test in mice, which exhibited a dose-dependently antagonized antinociception formed by the μ OR/ δ OR agonists CYM51010 and Deltorphan-II, without antagonizing the monomer agonists DAMGO and DSLET. Interestingly, **1.29** was also observed to sharply reduce withdrawal behavior in models of acute and chronic morphine dependence.

These data strongly suggest that **1.29** is a first-in-class selective and high affinity/potency μ OR/ δ OR heterodimer antagonist both in vitro and in vivo.

Figure 35. Bivalent μ OR/ δ OR antagonist ligands.

Busnelli et al.[156] reported bivalent ligands **1.30a** and **1.30b** comprising two identical oxytocin-mimetics (Figure 36) that induced a three order magnitude boost in G-protein signaling of oxytocin receptors (OTRs) in vitro and a 100- and 40-fold gain in potency in vivo in the social behavior of mice and zebrafish.

Figure 36. Bivalent OTR ligands **1.30a** and **1.30b** with high potency both *in vitro* and *in vivo*.

Through receptor mutagenesis and interference experiments with synthetic peptides mimicking transmembrane helices (TMH), they show that such superpotent behavior follows from the binding of the bivalent ligands to dimeric receptors based on a TMH1-TMH2 interface. Furthermore, in this arrangement, only the analogues with a well-defined spacer length (~ 25 Å) precisely fit inside a channel-like passage between the two protomers of the dimer. The newly discovered oxytocin bivalent ligands represent a powerful tool for targeting dimeric OTR in neurodevelopmental and psychiatric disorders and, in general, provide a framework to untangle specific arrangements of GPCR dimers.

I.2.8 Conclusion

Bivalent ligands are defined as compounds that contain two pharmacophores linked by an appropriate spacer. The design of such molecules requires the selection of potent and subtype-selective lead pharmacophores, appropriate attachment points to connect the spacer, and the length and composition of the spacer group. This overview mainly focused on the design of bivalent ligands recently described in the literature and used as specific pharmacological tools to investigate GPCR dimerization.

The advantages of the bivalent approach are numerous, including enhanced potency and receptor subtype specificity. However, the use of bivalent ligands as potential pharmacotherapeutics is limited by problematic molecular properties, such as high molecular weight and lipophilicity. In addition, the linker must be attached to the pharmacophore in a position that tolerates structural modification.

All the examples mentioned above strongly suggest that the length and nature of the linker are crucial factors for the optimal ligand-receptor interactions, which depend on the properties of the selected pharmacophores and binding sites of GPCRs.

Overall, these compounds possess great potential as pharmacological tools to investigate the GPCR dimerization *in vitro* and *in vivo*.

CHAPTER II

OBJECTIVES

II. OBJECTIVES

Bivalent ligands possess great potential as pharmacological tools to investigate GPCR dimerization both in vitro and in vivo, and may evolve to promising drug candidates for diverse diseases.

The main goal of this PhD study is to design and synthesize bivalent GPCR ligands to study new receptor-receptor interactions. In a first study (Chapter III), we aim to synthesize a series of heterobivalent μ OR -D₂-likeR ligands as pharmacological tools to study μ OR-D₂-likeR heteromers. D₂-likeR agonist/antagonist and μ OR agonist/antagonist will be linked through PEG spacers of variable length to probe the best interaction with the μ OR-D₂-likeR heteromer. The binding properties of these compounds will be determined by radioligand binding studies in membrane preparations and intact cells. Furthermore, MAPK phosphorylation and β -arrestin2 recruitment assays will be performed to assess the pharmacological response of the ligands for D₂-likeR and μ OR, respectively. This study will involve cells expressing the μ OR and D₂-likeR, separately, as well as cells co-expressing both receptors.

As depicted in Figure 1, the bivalent ligands will be derived from a 6-hydromorphamine (to which we will gain access from hydromorphone) and the structurally related μ OR antagonist 6-naltrexamine (NTA). As D₂-likeR ligands we plan to use 1,4-disubstituted aromatic piperazines (1,4-DAPs) and 5-hydroxy-2-(dipropylamino)tetralin (5-OH-DPAT) that will be equipped with an appropriate alkyne ligation handle.

Figure 1. Designed heterobivalent ligands of D₂-likeR and μ OR

In a next study (Chapter IV), we plan to design and synthesize bivalent D₂-likeR agonist/antagonist and mGluR5 antagonist ligands to study the mGluR5-D₂-likeR heteromers. For this study, we will explore different types of spacers including PEG linkers, alkyl linker, and tertiary amine spacers of varying length to investigate the effect of the length and nature of the spacers on binding affinity and functional

activity. The binding properties of these compounds will be determined by radioligand binding assays. Moreover, cAMP and MAPK phosphorylation will be measured to assess the signal transduction for both D₂-likeR and mGluR5. Experiments to evaluate the behaviour of the heterobivalent ligands to dimeric receptors will be performed in cells coexpressing mGluR5 and D₂-likeR. The target bivalent ligands of mGluR5-D₂-likeR are shown in Figure 2.

Figure 2. Designed bivalent ligands of D₂-likeR and mGluR5

Fluorescently labeled ligands have been developed to study receptor localization, trafficking, and signaling processes via fluorescence imaging. They are also employed in fluorescent binding assays, where they offer advantages over radioligands which suffer from possible health risks and legal and disposal costs.

In Chapter IV, we will use alkyne functionalized boron dipyrromethene (BODIPY) dyes to construct possible fluorescent mGluR5 ligands (Figure 3). These ligands will be assessed by NanoBRET.

Figure 3. Designed fluorescent mGluR5 ligands equipped with BODIPY dyes.

CHAPTER III

Design, synthesis and biological evaluation of bivalent ligands targeting Dopamine D₂-like receptors and the μ -opioid receptor

The content of this chapter was partially derived from:

Qian, M.; Vasudevan, L.; Huysentruyt, J.; Risseuw, M. D. P.; Stove, C.; Vanderheyden, P. M. L.; Van Craenenbroeck, K.; Van Calenbergh, S. *ChemMedChem* **2018**, *13*, 944 – 956.

β -arrestin2 recruitment to μ OR was partially assessed by Lakshmi Vasudevan. Ligand binding assay for D₂R using [³H]raclopride was carried out with the help of Jelle Huysentruyt.

III. DESIGN, SYNTHESIS AND BIOLOGICAL EVALUATION OF BIVALENT LIGANDS TARGETING DOPAMINE D₂-LIKE RECEPTORS AND THE μ -OPIOID RECEPTOR

III.1. Abstract

Currently, there is mounting evidence that intermolecular receptor-receptor interactions may result in altered receptor recognition, pharmacology and signaling. Heterobivalent ligands have been proven useful molecular probes for confirming and targeting heteromeric receptors. This paper describes the design and synthesis of novel heterobivalent ligands for dopamine D₂-like receptors (D₂-likeR) and the μ opioid receptor (μ OR) and their evaluation using ligand binding and functional assays. Interestingly, we identified a potent bivalent ligand that contains a short 18-atom linker and combines good potency with high efficacy both in β -arrestin2 recruitment for μ OR and MAPK-P for D₄R. Furthermore, this compound was characterized by a biphasic competition binding curve for the D₄R- μ OR heterodimer, indicative of a bivalent binding mode. As this compound possibly bridges the D₄R- μ OR heterodimer, it could be used as a pharmacological tool to further investigate the interactions of D₄R and μ OR.

III.2. Introduction

G protein-coupled receptors (GPCRs) represent the largest family of membrane proteins. About half of the clinically used drugs today recognize GPCRs. It is now widely accepted that different GPCRs can interact with each other and form complexes, so called heteromers. The first hypothesis on GPCR heteromers was already raised in the early eighties after observations of neuropeptide-monoamine receptor-receptor interactions.^{1,2} The existence of heteromers was confirmed almost twenty years later for two non-functional GPCR monomers, gamma amino butyric acid (GABA) receptors, GABAB1 and GABAB2, which assemble at the cell surface in a signaling heterodimer, the GABAB receptor.³ Now, dimerization has been described for many GPCRs in *in vitro* settings although evidence in native tissue is still sparse.^{4,5}

In classical pharmacology allosteric mechanisms were only discussed in terms of intramolecular interactions within a receptor between orthosteric and allosteric sites. Nowadays, there is mounting evidence that also intermolecular receptor-receptor interactions may result in altered receptor recognition, pharmacology and signaling. Heterobivalent ligands have been proven useful molecular probes for confirming and targeting heteromeric receptors,^{6,7,8} such as κ - and δ -opioid receptor heteromers.⁷

There are five dopamine receptor subtypes that can be divided into two distinct subfamilies: D₁-like (D₁R and D₅R) and D₂-like (D₂R, D₃R and D₄R). In this study we focus on the heterodimerization of the dopamine D₂-like receptors (D₂-likeR) and the μ opioid receptor (μ OR). D₂-likeR and μ OR are GPCRs,

expressed in the brain, which play a major role in schizophrenia, Parkinson's disease, addiction and pain. Heterobivalent ligands are valuable tools to demonstrate the existence of receptor heteromers even in native tissue and can be used to study a specific GPCR dimer behavior without any receptor modification.^{9,10,11} Such compounds may eventually also evolve to useful pharmacological agents.¹⁰ Heterobivalent ligands with a spacer of optimal length are envisaged to exhibit a potency that is different from that derived from its two monovalent pharmacophores and may allow the targeting of certain heteromeric subtypes, increasing the selectivity of drug action.^{11,12,13}

The dopaminergic and opioid peptide system are pharmacological targets for the treatment of addiction and chronic pain. They show an impressive co-distribution in many nuclei of the brain, which enables intermolecular receptor-receptor interactions^{14,15} that may be relevant for the treatment of addiction and chronic pain. *In vivo* studies indicate that there exists a cross-regulation between the D₂-likeR and the μ OR. Activation of dopaminergic receptors causes a transient reduction of the μ OR immunoreactivity. Additionally, D₂-likeR/ μ OR interactions also modulate morphine-induced upregulation of certain transcription factors c-Fos, δ FosB and P-CREB.^{16,17,18,19} These results can be explained by the existence of direct D₂-like-R- μ OR interactions. Furthermore, we have identified heterodimerization of D₂R- μ OR and D₄R- μ OR by co-immunoprecipitation (co-IP) and bioluminescence resonance energy transfer (BRET) studies in mammalian transfected cells (unpublished results). Therefore, all results discussed above indicate that D₂-likeR (especially D₂R and D₄R) and μ OR heterodimers could be potentially therapeutic targets for the treatment of addiction and chronic pain.

Here we report the design and synthesis of a series of heterobivalent μ OR agonist/antagonist-D₂-likeR agonist/antagonist ligands as pharmacological tools to further study μ OR-D₂-likeR (μ OR-D₂R and μ OR-D₄R) heteromers. In these compounds, the D₂-likeR agonist/antagonist and the μ OR agonist/antagonist were linked through a spacer of variable length. The spacers were based on PEG unit repeats, and their size was varied (from 18 to 24 atoms) to obtain the best interaction with the μ OR-D₂-likeR heteromers. The binding properties of these compounds were determined by radioligand binding studies in membrane preparations and intact cells. Furthermore, MAPK phosphorylation and β -arrestin2 recruitment assays were performed to test the pharmacological response of the ligands for D₂-likeR and μ OR, respectively. Experiments to evaluate the binding of the heterobivalent ligands to μ OR and D₂-likeR were performed in cells expressing both μ OR and D₂-likeR.

III.3. Design of heterobivalent ligands based on structure of D₂-likeR ligands and μ OR ligands

As depicted in Figure 1, the bivalent ligands were derived from the μ OR specific agonist hydromorphone (HM) and the structurally related μ OR antagonist naltrexone (NTX). As D₂-likeR ligands we used the antagonist 1,4-disubstituted aromatic piperazines (DAPs, **3.03**)²⁰ and the agonist 5-

hydroxy-2-(dipropylamino)tetralin (DPAT, **3.07**)¹¹ that were equipped with an appropriate ligation handle.

Figure 1. Designed heterobivalent ligands.

The dimeric ligands were constructed around PEG spacers of variable length that were equipped with a carboxylic acid on one and an azide on the other end (Figure 2). The use of PEG linkers precludes cumulative incremental increases in hydrophobicity that would occur upon homologation if an alkyl chain were employed. Using existing procedures both opioid ligands **3.01a** and **3.01b** were converted to their corresponding 6'-*R*-amino derivatives **3.02a** and **3.02b**. The introduced amine groups allow coupling to the PEG spacers via an amide bond, whereas the azido group on the PEG linker allows facile connection to the alkyne derived dopamine ligands via a copper-catalyzed azide–alkyne cycloaddition (CuAAC) reaction. The choice of the position and nature of the attachment points for linking the two pharmacophore units to the spacer relies on two criteria: the feasibility of the chemical modification and the compatibility of the modification with the biological activity (SAR data) of the pharmacophore.

Figure 2. Overview of used monovalent ligands and spacer molecules with appropriate ligation handles.

As indicated above, the selected D₂-likeR ligands need to be functionalized with an alkyne moiety to allow conjugation to the azide group of the PEG linkers. The intrinsic activity of DAPs for D₂-likeR is determined by an aromatic headgroup and an amine moiety, which forms a strong hydrogen bond to the crucial Asp3.32 residue in the transmembrane helix 3 (TM3) of D₂R.²⁰ A lipophilic appendage is necessary for enhancing ligand affinity. Because proper elongation of this appendage is expected to lead to the “entrance region” of the receptor and from there to the binding pocket of a neighboring protomer, the para-position of an aromatic moiety terminating this appendage is considered an appropriate point of attachment for a linker unit.²⁰ Vanilline allows for easy introduction of an alkyne group in para-position, while reductive amination permits coupling to the phenylpiperazine moiety.

DPAT is a prototypical D₂R/D₃R agonist suitable for constructing bivalent ligands.²¹ Site-directed mutagenesis has demonstrated that the 2-amino tetralin moiety interacts with an agonist binding domain involving TM3 and TM5 for activation of either D₂R or D₃R. The basic nitrogen and the 5-OH group are critically important for binding affinity. A known aniline derivative of DPAT¹¹ was coupled with 4-pentynoic acid to afford compound **7** with an alkyne group for click reaction.

III.4. Results and Discussion

III.4.1. Chemistry

III.4.1.1 Individual components of the bivalent ligands

As μ OR ligands the known *R*-amines **3.02a** and **3.02b** were prepared from NTX (**3.01a**) and HM (**3.01b**) respectively according to published procedures.²² Briefly, compounds **3.01a** and **3.01b** were converted to the corresponding oximes, which were reduced to 6*R*-amines **3.02a** and **3.02b** in the presence of ZrCl₄ and NaBH₄. Although previous studies showed little stereoselectivity in opioid binding for 6*R* versus 6*S* amine diastereomers,²³ the predominant *R*-diastereomers were separated from their *S*-epimers by silica gel chromatography, to facilitate further characterization.

For the synthesis of the first alkyne functionalized D₂-likeR ligand, DPAT (**3.07**), commercially available 5-methoxyl-2-tetralone (**3.04**) was converted to the 1,2,3,4-tetrahydronaphthalen-2-amine derivative **3.05** in 4 steps following existing procedures.¹¹ Arylamine **3.05** was coupled with 4-pentynoic acid to give amide **3.06**. Deprotection of the methyl ether with Me₂SBF₃ in CH₂Cl₂ gave the desired compound **3.07** (Scheme 1). The alkyne functionalized D₂-likeR ligand DAP (**3.03**) was synthesized starting from vanillin as described earlier by Kühhorn et al.²⁰ The bifunctional PEG linkers were prepared as described earlier.^{24,25,26}

Scheme 1. Reagents and conditions: a) 4-pentynoic acid, (3-dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride, triethylamine, CH_2Cl_2 , RT, overnight; b) Me_2SBF_3 , CH_2Cl_2 , RT, overnight.

III.4.1.2 Bivalent ligands synthesis.

The bivalent ligands were generated by first condensing each of the two μOR ligands with each of the three PEG linkers in the presence of the coupling agent EDC and triethylamine to yield the six intermediate azides **3.11a-f** (Scheme 2). The series of bivalent ligands was finalized by conjugating each of the six azides to both DPAT and DAP through CuAAC (Scheme 3). This yielded a concise series of 12 bivalent D_2 -likeR- μOR ligands in which each of the sets of ligands and the three linkers are systematically represented.

Scheme 2. Reagents and conditions: a) (3-dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride, 1-hydroxybenzotriazole, triethylamine, CH_2Cl_2 .

Scheme 3. Reagents and conditions: a) sodium ascorbate, $CuSO_4$, triethylamine, tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine, dimethylformamide.

III.4.2. Ligand binding assays

III.4.2.1 Evaluating the binding of the bivalent ligands to the D_2 -likeR

A saturation binding assay for [3H]spiperone, a non-selective antagonist of D_2 -likeR, was described previously.^{27,28} Here we performed a competition assay to evaluate the binding of the bivalent ligands to the D_2 -likeR D_2R and D_4R . First the binding affinity of the bivalent ligands **3.12a-f** and **3.13a-f** along with their alkynylated DAP and DPAT precursors **3.03** and **3.07** was measured by displacement of [3H]spiperone from the D_4R expressed in HEK 293T cells, indicating that all the bivalent ligands bind to the D_4R (Table 1). However, a clear reduction in the D_4R binding affinities of the bivalent ligands was detected when compared with the alkynes **3.03** and **3.07**. Compound **3.12d** with a short spacer length (18-atom) showed a slightly higher affinity for D_4R than **3.12e** and **3.12f**. This trend was also apparent for the other bivalent ligands (**3.12a**, **3.13a** and **3.13d**) possessing the same spacer as **3.12d**. In a next step we wanted to compare the affinity of the bivalent ligands for D_4R in the absence and presence

of overexpressed μ OR. Unexpectedly, no major differences in K_i values were found between both experimental set-ups, except for **3.12d**. Interestingly, a biphasic competition curve was observed for **3.12d** from which two individual affinity constants could be derived ($K_{i \text{ high}} 1.2 \pm 0.3$ nM and $K_{i \text{ low}} 207 \pm 51$ nM, Figure 3a). Such biphasic competition-binding curves are indicative of a bivalent binding mode.¹¹ Specifically, the high-affinity K_i value represents a bivalent receptor-bridging binding mode of **3.12d** to D₄R/ μ OR heterodimer, whereas the low-affinity K_i value reveals a monovalent-binding mode to D₄R. Bivalent ligand **3.12d** thus displays a 170-fold preference for the high-affinity bivalent interaction with the D₄R/ μ OR heterodimer over monovalent-binding mode to D₄R.

By following the same approach and still using [³H]spiperone as the radioligand, we also tested the affinity of the bivalent ligand **3.12d** and its corresponding monovalent ligand **3** to the D₂R and D₂R- μ OR receptors. The affinities of compound **3.12d** to D₂R and D₂R- μ OR decreased 3-fold compared to the ligand **3.03** for both receptors (Table 2). Unfortunately, we only obtained a monophasic competition-binding curve for **3.12d** to D₂R- μ OR and no major differences in binding affinity were observed between cells expressing only D₂R and cells expressing both D₂R and μ OR (Figure 3b).

Next, following a similar protocol, we determined the affinity of monomeric ligand **3.03** and bivalent ligand **3.12d** on cells expressing D₂R and D₂R- μ OR, utilizing an alternative radioligand, i.e. [³H]raclopride. Raclopride that acts as a selective D₂R antagonist is more hydrophilic and has substantially less non-specific binding in intact cells as compared with spiperone. Furthermore it is not cell permeable, rendering the assay possibly more sensitive as binding of the radioligand to be displaced is restricted to receptors in the plasma membrane. In this experiment (Table 3) the affinities of **3.12d** to D₂R and D₂R- μ OR were 32.4 ± 8.5 nM and 38.6 ± 3.2 nM, respectively, while the affinities of the monovalent alkyne **3.03** were 43.1 ± 9.0 nM and 49.9 ± 5.8 nM, respectively. Still, only one-site binding curves for **3.12d** were obtained from cells monoexpressing D₂R and cells coexpressing D₂R and μ OR (Supporting information). The saturation binding data for [³H]raclopride can be found in Supporting Information. Interestingly, we found that the affinity of **3.12d** for D₄R decreased 100-fold relative to the monovalent ligand **3**, while its K_i value for D₂R only decreased three-fold.

Table 1. Binding affinities (K_i) for D₄R and D₄R- μ OR.^[a]

Compd	R ₁	R ₂	n	D ₄ R	D ₄ R- μ OR
				K_i (nM)	K_i (nM)

3.13f	H	CH ₃	5	199 ± 16	493 ± 11

[a] Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [³H]spiperone binding to HEK293T D₄R and HEK293T D₄R-μOR membranes. All values are expressed as the mean ± SEM of three independent assays using 11 different concentrations of ligands, each performed in duplicate. [b] not determined.

Table 2. Binding affinities (K_i) for D₂R and D₂R-μOR.^[a]

Compound	K_i (nM) for D ₂ R	K_i (nM) for D ₂ R-μOR
3.03	22 ± 5	32 ± 11
3.12d	62 ± 3	101 ± 10

[a] Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [³H]spiperone binding to HEK293T D₂R and HEK293T D₂R-μOR membranes. All values are expressed as the mean ± SEM of at least two independent assays.

Figure 3. Representative competition curves for bivalent ligand **3.12d**. D₂-likeR binding of the bivalent ligand **3.12d** was measured by displacement of the radiolabeled [³H]spiperone from membranes of HEK293T cells coexpressing D₄R/μOR (or D₂R/μOR) or monoexpressing D₄R (or D₂R) only. (a) D₄R binding of **3.12d** in the presence (filled squares, $K_{i \text{ high}}$ 1.2 ± 0.3 nM, $K_{i \text{ low}}$ 207 ± 51 nM) or absence (open squares, K_i 184 ± 35 nM) of μOR. (b) D₂R binding of **3.12d** in the presence (filled circles, K_i 101 ± 10 nM) or absence (open circles, K_i 62 ± 3 nM) of μOR. Data points represent the mean \pm SEM of three independent assays, each performed in duplicate.

Table 3. Binding affinities (K_i) for D₂R and D₂R-μOR.^[a]

Compound	K_i (nM) for D ₂ R	K_i (nM) for D ₂ R-μOR
3.03	43.1 ± 9.0	49.9 ± 5.8
3.12d	32.4 ± 8.5	38.6 ± 3.2

[a] Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [³H]raclopride binding to HEK293T D₂R and HEK293T D₂R-μOR intact cells. All values are expressed as the mean \pm SEM of at least two independent experiments.

III.4.2.2 Evaluating the binding of the bivalent ligands to μOR

We performed competitive receptor binding assays in cell membranes expressing μOR to determine the binding affinity of bivalent ligands, using the tracer [³H]diprenorphine, which is a nonselective opioid antagonist. Saturation binding assays showed that the K_d value and B_{max} of [³H]diprenorphine were 0.21 ± 0.064 nM and 489 ± 28 fmol/mg for μOR, respectively. In the competition assay the binding affinities for the monovalent ligands HM and NTX were 4.4 ± 0.21 nM and 7.8 ± 0.16 nM, respectively (Table 4). Compounds **3.12a-c** and **3.13a-c**, which were derived from NTX, exhibited a binding affinity for μOR comparable to NTX. Whereas, bivalent ligands **3.12b** and **3.13b** with a 21-atom spacer displayed relatively lower K_i values than the other NTX-based ligands. HM-based bivalent ligands

3.12d-f and **3.13d-f** showed a small reduction in the binding affinities for μ OR compared to the corresponding monovalent compound HM, except for **3.12e** (3.7 ± 0.02 nM) and **3.13e** (7.2 ± 0.53 nM) with a medium spacer length (21 atoms). Therefore, the affinities of bivalent ligands with a medium length of spacer (21 atoms) to μ OR were relatively higher than the other ligands with shorter (18 atoms) or longer linkers (24 atoms).

Table 4. Binding affinities (K_i) for μ OR.^[a]

Compd	R ₁	R ₂	n	K_i (nM)
Hydromorphone	H	CH ₃	-	4.4 ± 0.21
Naltrexone	OH	CH ₂ cPr	-	7.8 ± 0.16
3.12a	OH	CH ₂ cPr	3	6.3 ± 1.1
3.12b	OH	CH ₂ cPr	4	4.6 ± 0.25
3.12c	OH	CH ₂ cPr	5	9.2 ± 0.41
3.13a	OH	CH ₂ cPr	3	7.5 ± 0.95
3.13b	OH	CH ₂ cPr	4	3.8 ± 0.84
3.13c	OH	CH ₂ cPr	5	7.6 ± 0.39
3.12d	H	CH ₃	3	16 ± 0.87
3.12e	H	CH ₃	4	3.7 ± 0.02
3.12f	H	CH ₃	5	11 ± 0.57
3.13d	H	CH ₃	3	13 ± 1.2
3.13e	H	CH ₃	4	7.2 ± 0.53
3.13f	H	CH ₃	5	17 ± 3.4

[a] Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [³H]diprenorphine binding to HEK293T μ OR. All values are expressed as the mean \pm SEM of three independent assays.

III.4.3. Functional assays

III.4.3.1 MAPK phosphorylation to study D₂-likeR activation by the newly developed bivalent ligands

The mitogen-activated protein kinase (MAPK) phosphorylation assay was used to define the functional activity of the bivalent ligands. The MAPK pathway, which includes the extracellular-signal regulated kinase (ERK) pathway, consists of an intracellular chain of proteins that transfer the signal from the cell surface receptor to the nuclear DNA or other subcellular targets causing cellular responses. Signaling molecules in this pathway communicate with each other by adding a phosphate group to the neighboring protein. This phosphorylation event functions as an “on/off” switch, leading to the activation or inhibition of the next signaling molecule in the chain.²⁹ The most commonly studied element of the MAPK pathway, initiated by GPCR activation, is the phosphorylation of p44/42 MAPK (ERK1/2).

In order to assess functional activation of the D₂R and D₄R by the above described bivalent ligands, we used a HEK293 cell line stably expressing the D₂R and D₄R, respectively.³⁰ Unexpectedly, the signal band of MAPK-P for D₂R was quite weak (see supporting information). Nevertheless, we found a strong immunoreactive band (Figure 4) for MAPK-P upon activation of D₄R with the agonist dopamine (DA), and with the alkynylated DAP (**3.03**) and DPAT (**3.07**). Next, all bivalent ligands were tested in this cell system (Figure 5 and Table 5). We can conclude that all bivalent ligands activate the MAPK signaling pathway. Interestingly, compound **3.12d** with an 18-atom linker (shown in Table 5) displayed modestly high potency ($EC_{50} = 0.12 \pm 0.04 \mu\text{M}$) and relatively high efficacy ($92 \pm 1\%$) as compared with the monovalent ligand **3.03** ($EC_{50} = 0.21 \pm 0.12 \mu\text{M}$, $E_{\text{max}} = 75 \pm 2\%$), while the potency of compounds **3.12a-c** decreased 8-16 fold compared to **3.03**. In addition, all the DAP-bond ligands, except for **3.12d**, showed a comparable efficacy ($E_{\text{max}} = 72\text{-}85\%$) relative to compound **3.03**. On the other hand, DPAT-based bivalent ligands had a potency ($EC_{50} = 0.45\text{-}0.95 \mu\text{M}$) and efficacy ($E_{\text{max}} = 86\text{-}108\%$) comparably to that of **7** ($EC_{50} = 0.37 \pm 0.17 \mu\text{M}$, $E_{\text{max}} = 100 \pm 3\%$). Overall, bivalent ligand **3.12d** with a short linker length (18 atoms) was the most potent compound to activate the MAPK phosphorylation of D₄R.

Figure 4. Stimulation of MAPK phosphorylation upon D₄R agonist treatment, as determined by immunoblotting assays. Cells were treated with serum-free media (SFM) for 12 h. Next, D₂-likeR agonists (10 μ M), SFM or vehicle control were added for 5 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. The results shown are representative of three independent experiments. DA=dopamine.

Figure 5. Efficacy of bivalent ligands to phosphorylate MAPK in HEK293 D₄R cells. Cells were treated with serum-free media (SFM) for 12 h. Next, D₂-likeR agonists (10 μ M) and SFM were added for 5 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. The top panel shows a representative result from three independent experiments; the bottom panel is given as mean \pm SD. DA=dopamine. Bivalent ligands were significantly different (* p < 0.05, ** p < 0.01, *** p < 0.001) compared to the control SFM by One-way ANOVA.

Table 5. Potency (EC_{50}) of D_2 -likeR agonists induced MAPK-P in HEK293 D_4 R cells

III.4.3.2 β -arrestin2 recruitment to μ OR

To assess activation of the μ OR, HEK 293 cell line was used to stably express the μ OR. Unfortunately, we did not obtain any good results from MAPK-P for μ OR (data not shown). Then we performed a β -arrestin2 recruitment assay based on the NanoLuc Binary Technology (NanoBiT).³¹ Our research group recently reported on the application of this assay for the monitoring of GPCR activation, via ligand induced interaction of β arr2 with CB1 and CB2 cannabinoid receptors.³² Here, we optimized this assay

for ligand induced interaction of β arr2 with μ OR. Agonists of μ OR, such as DAMGO, have previously been shown to induce robust receptor phosphorylation, β -arrestin2 recruitment and μ OR trafficking.^{33,34} On the other hand, morphine is a poor inducer of receptor phosphorylation, β -arrestin2 recruitment and internalization of μ OR. However, upon overexpression of G protein-coupled receptor kinase (GRK2) in cell culture, morphine gained the capacity to induce μ OR phosphorylation, accompanied by the rescue of β -arrestin2 recruitment.^{34,35}

To assess the ligand induced interaction of β -arrestin2 with μ OR, overexpression of GRK2 in cell culture was performed. Our results show that DAMGO induces a robust β -arrestin2 recruitment even in the absence of GRK2. On the other hand, HM could promote β -arrestin2 recruitment only when GRK2 was overexpressed in HEK 293 cells. Both results are in line with those found in the literature (see supporting information Figure 2).

Upon stimulation with a known agonist of μ OR, HM, μ OR-SmBiT showed a concentration dependent interaction with LgBiT- β arr2 in the presence of GRK2 (Figure 6). Also, for the bivalent ligands containing the agonistic HM-based monomer, concentration-dependence was obtained and EC_{50} values were determined as a measure of relative potency (Table 6 and Figure 6). Ranging from 12.73 nM to 57.06 nM, all the EC_{50} values of the bivalent ligands were comparable to that of the parent HM (EC_{50} = 30.09 nM). Amongst the DAP-based ligands, compound **3.12d**, having the shortest linker (18-atom), showed excellent potency (EC_{50} = 12.73 nM) and high efficacy ($85 \pm 3\%$). Remarkably, all DPAT-based ligands showed lower efficacies than DAP-bond ligands, with compound **3.13d**, having the same spacer as **3.12d**, displaying the lowest efficacy ($24 \pm 1\%$) amongst the DPAT-based ligands.

Figure 6. Concentration-dependent interaction of μ OR with β -arrestin2 upon stimulation with agonists of μ OR. Data are given as mean \pm SEM of at least two independent experiments.

Table 6. Potency (EC_{50}) and maximal effect of μ OR agonists on β -arrestin2 recruitment for μ OR.

Compd	R ₁	R ₂	n	EC ₅₀ (95% C.I.) nM ^[a]	% HM ^[b]
HM	H	CH ₃	-	30.09 (24.51-36.94)	100
3.12d	H	CH ₃	3	12.73 (7.612-21.28)	85 ± 3
3.12e	H	CH ₃	4	40.38 (30.41-53.61)	68 ± 1

[a] EC₅₀ values are presented as a measure of potency for β -arrestin2 recruitment. Data are given as EC₅₀ values (95% CI profile likelihood). [b] Percent maximal stimulation relative to the agonist HM at 10 μ M.

III.5. Conclusions

In summary, we have designed and synthesized a series of novel heterobivalent ligands based on the chemical structure of two distinct D₂-likeR ligands and a μ OR agonist and antagonist. Ligation of μ OR ligands does not perturb the affinity for μ OR. μ OR bivalent ligands derived from the HM agonist are still capable of activating the μ OR signaling pathway as demonstrated by β -arrestin2 recruitment. Furthermore, bivalent ligand **3.12d** containing the shortest linker (18-atom) showed excellent potency and high efficacy both in β -arrestin2 recruitment for μ OR and MAPK-P for D₄R. On the other hand, ligation of D₂-likeR ligands negatively influences the affinity for D₂R and D₄R when using [³H]spiperone as the radioligand. However, a biphasic competition-binding curve was observed for **3.12d** to D₄R- μ OR, which indicates a bivalent binding mode.^{11,43} Hence, compound **3.12d** could bridge the D₄R- μ OR heterodimer.

Unexpectedly, we were unable to identify bivalent ligands that show a biphasic binding mode or a significant increase in affinity for cells expressing both the D₂R and the μ OR, compared to cells that only express D₂R. This indicates that none of the bivalent ligands is capable of binding both receptors simultaneously, possibly owing to a suboptimal length or nature of the selected linkers, which, however, were based on the spacers of class A GPCR bivalent ligands.^{20,36} On the other hand it cannot be excluded that subtle differences such as differences in the dissociation rate of the ligands remain undetected by comparing equilibrium dissociation constants. In a study investigating adenosine A₃ receptors, ligand

binding kinetics were found to be influenced in membrane microdomains as a consequence of receptor dimerization.³⁷

While future studies will try to address these shortcomings, the current study already gives access to the monomeric ligands that are equipped with appropriate ligation handles to construct second-generation bivalent ligands with alternative spacers. In conclusion, the present results provide useful insights into development of new bivalent ligands as tools to investigate the μ OR-D₄R heterodimer.

III.6. Experimental Section

III.6.1. Chemistry

All reactions described were performed under an N₂ atmosphere and at ambient temperature unless stated otherwise. All reagents and solvents were purchased from Sigma-Aldrich (Diegem, Belgium), Fisher Scientific (Merelbeke, Belgium), TCI Europe (Zwijndrecht, Belgium) or Apollo Scientific (Bredbury, Stockport, United Kingdom) and used as received. NMR solvents were acquired from Eurisotop (Saint-Aubin, France). Reactions were monitored by TLC analysis using TLC aluminium sheets (Macherey-Nagel, Alugram Sil G/UV254) with detection by spraying with a solution of (NH₄)₆Mo₇O₂₄·4H₂O (25 gL⁻¹) and (NH₄)₄Ce(SO₄)₄·2H₂O (10 gL⁻¹) in H₂SO₄ (10 % aq.) followed by charring or an aqueous solution of KMnO₇ (20 gL⁻¹) and K₂CO₃ (10 gL⁻¹) or an ethanolic solution of ninhydrin (2 gL⁻¹) and acetic acid (1% v/v) followed by charring. Solution pH values were estimated using universal indicator paper (Merck). Silica gel column chromatography was performed using a Grace Reveleris X2 system and the corresponding silica gel cartridges. ESI-HRMS spectra were measured with a Waters LCT Premier XE Mass spectrometer calibrated using leucine enkephalin as an external standard. ¹H- and ¹³C-APT-NMR spectra were recorded with a Varian Mercury-300BB (300/75 MHz) spectrometer. Chemical shifts are given in ppm (δ) relative to tetramethylsilane as an internal standard (¹H NMR) or the NMR solvent (¹³C NMR). Coupling constants are given in Hertz (Hz). Weak signals in ¹³C NMR are indicated as (w). LC-MS analyses were carried out on a Waters AutoPurification System equipped with PDA and ESI-MS detection and using a Waters CORTECS C18 Column (4.6×100 mm, 2.7 μ m) and a water/acetonitrile/formic acid linear gradient system at a flow rate of 1.44 mLmin⁻¹.

General procedure 1: Carbodiimide-mediated amide formation.

To a solution of (3-Dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride (1.5 eq.) and 1-hydroxybenzotriazole (1.4 eq.) in CH₂Cl₂ was added a solution of the PEG spacer (1.2 eq.) in CH₂Cl₂ (0.2 M) and cooled to 0°C under an argon atmosphere. After 15 min at 0°C, amines **3.02a-b** (1.0 eq.) were added and triethylamine (2 eq.) was added dropwise; the reaction was slowly warmed to room temperature and stirred overnight. The reaction was diluted with CH₂Cl₂, washed successively with

water, HCl (5% aq.), NaHCO₃ (sat. aq.), NaCl (sat. aq.), dried over Na₂SO₄, filtered and solvent was evaporated under reduced pressure. The crude product was purified by silica gel chromatography (NH₄OH/MeOH/CH₂Cl₂, 1:5:94 v/v/v) to yield the amides **3.11a-f**.

General procedure 2: Copper mediated azide-alkyne cycloaddition.

To a solution of the intermediate azide (1.0 eq.) in dimethylformamide (0.1 M) was added the alkyne (1.5 eq.), sodium ascorbate (1.0 eq., 0.5 M), CuSO₄ (0.2 eq., 0.05 M), triethylamine (3.0 eq.) and a catalytic amount of tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine. The reaction mixture was stirred overnight at room temperature in the dark under an argon atmosphere. The solvent was evaporated under reduced pressure and the residue was redissolved in water and extracted with CH₂Cl₂. Then combined organic fractions were pooled, washed with brine and dried over Na₂SO₄. The crude compound was purified by silica gel chromatography (NH₄OH/MeOH/CH₂Cl₂, 1:5:94 v/v/v) to give the final compound as a white solid (yield, 40-57%).

N-(4-(2-((5-methoxy-1,2,3,4-tetrahydronaphthalen-2-yl)(propyl)amino)ethyl)phenyl)pent-4-ynamide
(**3.06**)

To a solution of (3-Dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride (1.1 g, 4.92 mmol) in CH₂Cl₂ (20 mL) was added a solution of 4-pentynoic acid (0.39 g, 3.93 mmol) in CH₂Cl₂ (5 mL) followed by a solution of **3.05** (1.1 g, 3.28 mmol) in CH₂Cl₂ (5 mL). The mixture was cooled to 0 °C and triethylamine (0.68 mL, 4.92 mmol) was added dropwise; the reaction was slowly warmed to room temperature and stirred overnight. The reaction was diluted with CH₂Cl₂, washed successively with water, HCl (5% aq.), NaHCO₃ (sat. aq.), NaCl (sat. aq.), dried over Na₂SO₄, filtered and solvent was evaporated under reduced pressure. The crude product was purified by silica gel chromatography (Hexane/EtOAc, 3:2 v/v) to give **3.06** as a pale yellow solid (1.32 g, 95%). ¹H NMR (300 MHz, CDCl₃) δ ppm 7.42 (d, *J* = 8.4 Hz, 2H), 7.15 (d, *J* = 8.4 Hz, 2H), 7.07 (t, *J* = 7.9 Hz, 1H), 6.69 (d, *J* = 7.8 Hz, 1H), 6.62 (d, *J* = 8.1, 1H), 3.78 (s, 3H), 3.04-2.91 (m, 2H), 2.91-2.80 (m, 1H), 2.79-2.63 (m, 6H), 2.63-2.53 (m, 7H), 2.05 (d, *J* = 3.2 Hz, 2H), 1.61-1.41 (m, 3H), 0.88 (t, *J* = 7.3 Hz, 3H). ¹³C NMR (75 MHz, CDCl₃) δ 169.4, 157.2, 137.9, 137.0, 135.7, 129.2, 126.1, 125.2, 121.6, 120.1, 106.9, 82.9, 69.5, 56.7, 55.2, 52.9, 52.6, 36.1, 35.4, 32.3, 25.7, 23.8, 22.2, 14.8, 11.9. HRMS (ESI) *m/z*: calculated for C₂₇H₃₅N₂O₂ [M+H]⁺ 419.2699; found 419.2705.

N-(4-(2-((5-hydroxy-1,2,3,4-tetrahydronaphthalen-2-yl)(propyl)amino)ethyl)phenyl)pent-4-ynamide
(**3.07**)

To a solution of **3.06** (1.05 g, 2.51 mmol) in CH₂Cl₂ (20 mL) was added boron trifluoride methyl sulfide complex (4.77 mL, 45.21 mmol). The reaction was stirred overnight under nitrogen at room temperature. The mixture was treated with a saturated aqueous NaHCO₃ solution, extracted with CH₂Cl₂, dried over

Na_2SO_4 and the solvent was evaporated under reduced pressure. The crude product was purified by silica gel chromatography (Hexane/EtOAc, 1:1 v/v) to yield **3.07** as a white foam (750 mg, 74%). ^1H NMR (300 MHz, CDCl_3) δ ppm 7.41 (d, $J = 8.4$ Hz, 2H), 7.14 (d, $J = 8.4$ Hz, 2H), 6.97 (t, $J = 7.8$ Hz, 1H), 6.66 (d, $J = 7.5$ Hz, 1H), 6.59 (d, $J = 7.8$ Hz, 1H), 3.02-2.94 (m, 2H), 2.90-2.82 (m, 1H), 2.79-2.66 (m, 6H), 2.62-2.53 (m, 7H), 2.05 (d, $J = 3.2$ Hz, 2H), 1.66-1.56 (m, 1H), 1.53-1.46 (m, 2H), 0.89 (t, $J = 7.3$ Hz, 3H). ^{13}C NMR (75 MHz, CDCl_3) δ ppm 169.1, 153.5, 138.3, 137.1, 135.4, 129.2, 126.3, 123.0, 121.6, 120.0, 111.9, 82.8, 69.7, 56.6, 52.7, 52.6, 36.2, 35.2, 32.2, 25.7, 23.5, 22.0, 14.8, 11.9. III.6.2. Plasmids and receptor fusion constructs

The plasmids HA D_{4.2} and HA D₂ were described previously.³⁸ The NanoBiT constructs (NB MCS1) and (NB MCS2) were procured from Promega. These plasmids encode for the split fragments of Nanoluciferase: LargeBiT (LgBiT) and SmallBiT (SmBiT). The human μOR was PCR amplified and SmBiT was cloned at the C-terminus of the receptor. A flexible linker (GSSGGGGSGGGGSSG) is present in between μOR and SmBiT.

In order to clone μOR -SmBiT, specific primers were generated with a *Hind*III restriction site at the 5' terminus and a *Xho*I site at the 3' terminus of the μOR coding sequence by removing the stop codon. PCR was performed with 20 ng of plasmid with *Pfu* DNA Polymerase (2.5 U/ μL , Thermo Fisher Scientific) according to the manufacturer's protocol. The reactions were performed in a MastercyclerTM Nexus Thermal Cycler (Eppendorf, Hamburg, Germany) and then purified using QIAquick Gel Extraction Kit (QIAGEN, Germany). The resultant amplicon and the vector (NB MCS2) were digested with *Hind*III and *Xho*I for 3 h at 37°C. The digested PCR product was cleaned using "High Pure PCR Product Purification Kit" (Roche, Germany) and then ligated into the corresponding digested NB MCS2. After transformation of the ligated product into competent MC 1061 "E. coli" strain, the ampicillin resistant clones were screened by performing PCR with primers against μOR . Furthermore, a digestion was performed with *Hind*III and *Xba*I, which are the restriction sites flanking μOR -SmBiT. The constructs were verified by sequencing. LgBiT-Barr2 has been previously described.³²

III.6.3. Cell culture and transfection

Human embryonic kidney (HEK) 293T cells were cultured in Dulbecco's modified Eagle's medium (DMEM; Invitrogen), supplemented with 10% fetal bovine serum, penicillin (100 U/ml), and streptomycin (100 µg/ml) in a controlled environment (37 °C, 98% humidity, 5% CO₂). For ligand binding experiments and β-arrestin2 recruitment assay, HEK293T cells were transiently transfected using the Polyethylenimine (PEI) method as described before.³⁰ A total amount of 10 µg of DNA was used for transfection of cells in one 10-cm dish. HEK293S cells stably expressing HA D_{4.2}R³⁰ were grown in DMEM/F12 (Gibco, Invitrogen) supplemented with 10% fetal bovine serum, penicillin (100 U/ml), streptomycin (100 µg/ml), and 0.5 mg/ml G418 (Geneticin, Gibco) in a controlled environment (37 °C, 98% humidity, 5% CO₂).

III.6.4. Membrane Preparation and Protein Determination.

Membrane suspensions from HEK293T cells transiently transfected with the receptors of interest were prepared as described previously.^{27,28} Cells were disrupted with a Polytron homogenizer for two 10 s periods in 10 volumes of ice-cold Tris-HCl buffer (50 mM, pH 7.4). Membranes were obtained by centrifugation at 16500g for 20 min at 4 °C, and the pellet was resuspended and centrifuged under the same conditions. The resulting pellet was stored at –80 °C and was washed once more as described above and resuspended in Tris-HCl buffer (50 mM, pH 7.4) for immediate use. Protein was quantified by the BCA method using bovine serum albumin dilutions as the standard.

III.6.5. [³H]Spiperone Binding.

Saturation binding assay for [³H]spiperone was performed as previously described.^{27,28} For competition binding assays, membranes (20 µg) were incubated in binding buffer (50 mM Tris-HCl containing 5 mM KCl, 1 mM EDTA, 1.5 mM CaCl₂ and 4 mM MgCl₂, pH 7.4) with 0.2 nM [³H] spiperone (specific activity = 76 Ci/mmol, PerkinElmer, USA) in the absence or presence of 11 different concentrations (0.1 nM-10 µM) of unlabeled ligands for 1 h at 22 °C. Nonspecific binding was determined in the presence of 1 µM haloperidol. Incubation was terminated by rapid filtration through GF/C glass-fiber filters (Whatman Schleicher and Schuell, Keene, NH) embedded in 0.1% polyethylenimine and mounted on a Brandel cell harvester. Filters were washed three times with cold 50 mM Tris-HCl, pH 7.4 buffer and transferred to vials containing 3 mL of scintillation cocktail to soak the filter overnight. The radioactivity counts were measured with a Tri-Carb 2800TR liquid scintillation analyzer (PerkinElmer).

III.6.6. [³H]Raclopride Binding.

[³H]raclopride saturation binding assay was performed as described before.³⁹ Briefly, a suspension of whole cells (corresponding to a total protein amount of 20 µg) were incubated with different

concentrations (0–20 nM) of [³H]raclopride in 50 mM Tris-HCl, pH 7.4 buffer (containing 5 mM KCl, 100 mM NaCl, 1.5 mM CaCl₂, 4 mM MgCl₂ and 1 mM EDTA) at 37°C for 1 h. For competitive binding experiments, 2.0 nM [³H]raclopride (specific activity = 73.8 Ci/mmol, PerkinElmer, USA) was incubated with 20 µg of whole cells in the absence or presence of varying concentrations (0.1 nM–10 µM) of unlabeled ligands at 37°C for 1 h. Nonspecific binding was determined in the presence of 1 µM haloperidol. Free and cell-bound ligand were separated by rapid filtration through GF/C glass-fiber filters (Whatman Schleicher and Schuell, Keene, NH) embedded in 0.1% polyethylenimine and mounted on a Brandel cell harvester. Filtration and measuring were as described above.

III.6.7. [³H]Diprenorphine Binding.

[³H]diprenorphine saturation binding assay was adapted from a published protocol.⁴⁰ Membranes (10 µg) were incubated with different concentrations (0–6 nM) of [³H]diprenorphine in 50 mM Tris-HCl, pH 7.4 buffer at 25°C for 1 h. For competitive binding experiments, 0.5 nM [³H]diprenorphine (specific activity = 25.8 Ci/mmol, PerkinElmer, USA) was incubated with 10 µg of membranes in the absence or presence of varying concentrations (0.1 nM–10 µM) of unlabeled ligands at 25°C for 1 h. Nonspecific binding was determined in the presence of 10 µM naloxone. Filtration and measuring were as described above.

III.6.8. Data Analysis.

Results are expressed as means ± SEM for at least three experiments, each performed in duplicate. Statistical analysis and curve fits of dose-response curves were performed using GraphPad Prism 7. Ki values were calculated by using the Cheng-Prusoff equation.⁴¹

III.6.9. MAPK phosphorylation

HEK293S cells stably expressing HA D_{4.2}R were seeded in 6-well plates at 400,000 cells per well. When the cells were 70% confluent, cells were starved overnight with serum free medium. The ligands (1 nM–10 µM) were added sequentially to the cells at the concentrations indicated in the legend for 5 min. To stop the reaction, medium was aspirated, the cells were placed on ice and washed with ice-cold PBS. RIPA buffer [150 mM NaCl; 50 mM Tris/HCl pH 7.5; 1 % NP-40; 0.1 % SDS; and 0.5 % deoxycholic acid sodium salt (Acros Organics: 218591000), protease inhibitors: aprotinin (2.5 µg/ml, Sigma-Aldrich: A6279), pefablock (1 mM, Sigma-Aldrich: 76307), leupeptin (10 µg/ml, Acros Organics: 328350050), and phosphatase inhibitor β-glycerol phosphate disodium salt pentahydrate (10 mM, Fluka BioChemika: 50020) was used to prepare the cell lysate for western blotting according to the protocol described before.⁴² After western blotting, the membrane was incubated with blocking buffer (LI-COR Biosciences) for 1h at RT. Then, primary antibody rabbit polyclonal phospho-p44/42 MAPK (1/2000) (Cell Signaling, cat. no. 9101L) or mouse monoclonal p44/42 MAPK (1/2000) (clone L34F12; Cell

Signaling, cat. no. 4696S) was added to develop the blot overnight at 4 °C. Next, the blot was washed with washing buffer (PBS + 0.05% Tween 20 from Sigma-Aldrich) for three times and then secondary antibodies goat anti-rabbit IRDye680 LT (1/10000) (cat. no. 926–68021, LI-COR Biosciences) or goat anti-mouse IRDye800 (1/10000) (cat. no. 926–32210, LI-COR Biosciences) were added for 1h at RT in the dark. The blot was washed three times with washing buffer and the fluorescent signal was detected with the Odyssey Infrared Imaging system. In the analysis, the phospho-p44/42 MAPK signal is normalized against the total p44/42 MAPK signal after quantification by Image J.

III.6.10. β -arrestin2 recruitment

HEK293T cells were seeded in 10-cm dishes with 2.5×10^6 cells/dish and transiently transfected with p μ OR-SmBiT (4 μ g), pLgBiT- β arr2 (1 μ g), pGRK2 (1 μ g) and pcDNA3 (4 μ g) per 10-cm dish. Forty-eight hours after transfection, the cells were washed with warm PBS, a cell suspension was prepared with warm HBSS and proteins were estimated by the bicinchoninic acid method (BCA, Thermo Scientific™) using bovine serum albumin dilutions as the standard. The cell suspension was added to a 96-well plate (100 μ l cell suspension in each well corresponding to 800 ng protein). The Nano-Glo Live Cell reagent, a nonlytic detection reagent containing the cell permeable furimazine substrate, was prepared by diluting the Nano-Glo Live Cell substrate 20 \times using Nano-Glo LCS Dilution buffer, and 25 μ l was added to each well. Subsequently, the plate was placed in the luminodetector (CLARIOstar) for measurement. Luminescence was monitored during the equilibration period until the signal was stabilized before adding the agonists of μ OR (0.1 nM-10 μ M, 14 μ l). After adding the test compounds, luminescence was continuously detected for 20-22 cycles. Solvent controls were run in all experiments.

Saturation assay for [³H]raclopride

Entry	Bmax fmol/mg	Kd nM
D ₂ R	722.7 ± 9.7	1.07 ± 0.05
D ₂ R-μOR	621.9 ± 14.1	1.05 ± 0.08

All values are expressed as the mean ± SEM of three independent assays performed in duplicate.

Binding affinities for D₂R and D₂R-μOR

Binding curves were obtained by competitive displacement of radiolabeled [³H]raclopride binding to HEK293T D₂R and HEK293T D₂R-μOR intact cells. Data are expressed as the mean ± SEM of at least two independent assays.

S4

Saturation assay for μ OR with [3 H]DAMGO

Entry	Bmax fmol/mg	K_d nM
μ OR	3315 ± 139	2.6 ± 0.3
μ OR-D ₂ R	1148 ± 54	1.8 ± 0.2

Binding affinities (K_i) for μ OR and D₂R- μ OR

Compound	K_i (nM) for μ OR	K_i (nM) for D ₂ R- μ OR
diprenorphine	0.16 ± 0.15	0.21 ± 0.11
3.13e	4.5 ± 1.7	4.8 ± 2.9

Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [3 H]DAMGO binding to HEK293T μ OR and HEK293T D₂R- μ OR cells membrane. All values are expressed as the mean \pm SEM of two independent assays performed in duplicate.

Immunofluorescence microscopy

Figure 3. Expression of D₂R and μ OR on cell membrane. HEK293T cells were seeded in 6-well plate with coverslips and transfected with FLAG- μ OR and HAD₂R in a 2:1 ratio. After 48 h post-transfection, cells were fixed, permeabilized and labeled with rabbit anti-HA and mouse anti-FLAG. Finally, cells were incubated with fluorescent secondary antibodies, anti-mouse Alexa Fluor 488 and anti-rabbit Alexa Fluor 594. μ OR and D₂R are visualized in green and red, respectively and μ OR-D₂R in the overlay picture. The results shown are representative of three independent experiments.

S6

HEK293T transiently transfected HA D₄R and FLAG- μ OR (1:2)

Figure 4. Expression of D₄R and μ OR on cell membrane. HEK293T cells were seeded in 6-well plate with coverslips and transfected with FLAG- μ OR and HAD₄R in a 2:1 ratio. After 48 h post-transfection, cells were fixed, permeabilized and labeled with rabbit anti-HA and mouse anti-FLAG. Finally, cells were incubated with fluorescent secondary antibodies, anti-mouse Alexa Fluor 488 and anti-rabbit Alexa Fluor 594. μ OR and D₄R are visualized in green and red, respectively and μ OR-D₄R in the overlay picture. The results shown are representative of three independent experiments.

Chromatographic analyses

Chromatographic analysis of representative bivalent ligands.[1] LC-MS analyses were carried out on a Waters Alliance 2695 XE separation Module by using a Phenomenex Kinetex EVO C18, 5 μ m 100x2.1mm and a gradient system of HCOOH in H₂O (0.1 %, v/v)/HCOOH in MeCN (0.1%, v/v) at a flow rate of 0.6 mLmin⁻¹, 100:0 to 0:100 (0 to 100 % MeCN) in 15 minutes. High-resolution spectra were recorded on a Waters LCT Premier XE Mass spectrometer and a 2996 Photodiode Array Detector, range 220 nm-400 nm.

CHAPTER IV

Synthesis toward bivalent ligands for the dopamine D₂ and metabotropic glutamate 5 receptors

The content of this chapter was partially derived from:

Qian, M.; Wouters, E.; Dalton, J. A. R.; Risseuw, M. D. P.; Crans, R. A. J.; Stove, C.; Giraldo, J.; Van Craenenbroeck, K.; Van Calenbergh, S. *J. Med. Chem.* **2018**, *61*, 8212–8225.

Ligand binding assays for D₂R were performed with the help of Elise Wouters. The cAMP assays were performed by Elise Wouters. Molecular docking study was carried out by James Dalton under supervision of Jesús Giraldo (Universitat Autònoma de Barcelona).

IV. SYNTHESIS TOWARD BIVALENT LIGANDS FOR THE DOPAMINE D₂ AND METABOTROPIC GLUTAMATE 5 RECEPTORS

IV.1. ABSTRACT

Recently, the existence of heteromers consisting of the metabotropic glutamate 5 receptor (mGluR5) and the dopamine D₂ receptor (D₂R) has been demonstrated in living cells and native tissue. This study describes the design and synthesis of heterobivalent ligands targeting this heterodimer and their evaluation via ligand binding and functional assays. Bivalent ligand **4.20a** with a linker consisting of 20 atoms showed 4-fold increase in affinity for cells coexpressing D₂R and mGluR5 compared to cells solely expressing D₂R. Likewise, the affinity of **4.20a** for mGluR5 increased 2-fold in cells in which both receptors were coexpressed. Additionally, **4.20a** exhibited a 5-fold higher mGluR5 affinity than its monovalent precursor **4.19a** in cells coexpressing D₂R and mGluR5. These binding results indicate that **4.20a** is able to bridge binding sites on both receptors constituting the heterodimer. Furthermore, **4.20a** showed about 4-fold and 7-fold higher potency in MAPK phosphorylation in stable cell lines coexpressing D₂R and mGluR5 compared to monovalent ligands **3.07** and **4.19a**, respectively. Likewise, cAMP assays revealed that **4.20a** had a 4-fold higher potency than **3.07** in the coexpressing cells. Furthermore, molecular modeling reveals that **4.20a** is able to simultaneously bind both receptors by passing between the TM5-TM6 interface and establishing six protein-ligand H-bonds. The above mentioned affinity, functional data and docking study suggest that **4.20a** holds promise to further study the interactions between D₂R and mGluR5.

IV.2. Introduction

The metabotropic glutamate receptors (mGluRs) constitute a family of G protein-coupled receptors (GPCR) characterized by the presence of large, extracellular, N-terminal orthosteric binding domains, which are activated by L-glutamate.[1],[2],[3] Based on sequence homology, receptor pharmacology and signal transduction pathways the eight mGluR subtypes are divided into three groups (Group I, II, and III).

Group I mGluRs (mGluR1 and mGluR5) are mainly localized postsynaptically and are extensively distributed in many brain regions, including the hippocampus, thalamic nuclei, and spinal cord. Stimulation of Gq protein coupled mGluR1 and mGluR5 leads to phosphoinositide (PI) hydrolysis and formation of the intracellular second messengers inositol triphosphate (IP₃), which induces intracellular Ca²⁺ release, and diacylglycerol (DAG), which stimulates protein kinase C activity (PKC).[3],[4],[5] In contrast, Group II (mGluR2 and mGluR3) and group III (mGluR4, mGluR6, mGluR7, and mGluR8) are primarily located presynaptically and negatively coupled to adenylyl cyclase to reduce intracellular cAMP levels upon stimulation.[6],[7],[8]

Excessive activation of mGluR5 has been shown to be involved in the development of neurodegenerative diseases like Alzheimer's,[9],[10] Parkinson's disease,[11],[12] or numerous CNS disorders including neuropathic pain,[13] anxiety and depression,[14] drug addiction[15] and fragile X syndrome.[16],[17]

Five dopamine receptor subtypes can be divided into two distinct subfamilies: D₁-like (D₁R and D₅R) and D₂-like (D₂R, D₃R, and D₄R). There is mounting evidence that GPCRs may form homo- and heteromers at the plasma membrane. Cabello *et al.* first suggested the existence of heterodimers of mGluR5 and D₂R in living cells using a fluorescence complementation assay. Additionally, bioluminescence resonance energy transfer, and sequential resonance energy transfer assays also allowed detecting receptor oligomers containing more than two protomers, in which the mGluR5 and D₂R also assembled with the adenosine A_{2A} receptor (A_{2A}R). Co-immunoprecipitation in native tissue confirmed the association of mGluR5, D₂R and A_{2A}R in rat striatum homogenates. Overall, these results indicate the occurrence of mGluR5-D₂R-A_{2A}R heteromers in living cells and support their presence in the GABAergic striatopallidal neurons, where they may represent important targets for the treatment of locomotion, neuropsychiatric disorders and drug addiction.[18],[19]

A recent study by Beggiato *et al.*[20] revealed a functional role for A_{2A}R, D₂R and the mGluR5 in regulating rat basal ganglia activity using dual-probe microdialysis in freely moving rats. The results suggested that A_{2A}R and mGluR5 interact synergistically in modulating the D₂R-mediated control of striatopallidal GABA neurons. D₂R appears to suppress synaptic delivery of mGluR5 by limiting Src family kinase (SFK)-mediated tyrosine phosphorylation of mGluR5 in rat striatum.[21] In the basal ganglia, mGluR5 negative allosteric modulators regulate the L-3,4-dihydroxyphenylalanine (L-DOPA) induced changes of D₂R, the associated signaling proteins ERK1/2 and Akt/GSK3 β and neuropeptides preproenkephalin and prodynorphin, as well as the A_{2A}R expression.[22] It is well known that cocaine increases both extracellular dopamine (DA) and glutamate levels in the nucleus accumbens (NAc) and that these effects are enhanced with repeated administration.[23]

Nowadays, heterobivalent ligands have emerged as valuable tools to demonstrate the existence of receptor heteromers without the need for receptor modification.[24],[25],[26] Heterobivalent ligands with a spacer of optimal length are envisaged to exhibit a potency that is different from that derived from its two monovalent pharmacophores.[26],[27],[28] Compounds able to modulate two GPCR dimers may eventually also evolve to useful pharmacological agents that target selected heteromeric subtypes, thereby potentially increasing selectivity.[25]

Here we report the design and synthesis of a series of mGluR5 negative allosteric modulators (NAMs)-D₂R agonist/antagonist heterobivalent ligands as pharmacological tools to study mGluR5-D₂R

heteromers. Towards this end ligands for the protomeric D₂R and the mGluR5 were conjugated through a spacer of variable length.

These bivalent ligands were evaluated in radioligand binding and functional assays both in cells in which the mGluR5 and D₂R were expressed separately and in cells co-expressing both target receptors.

IV.3. Results and Discussion

IV.3.1. Design of heterobivalent ligands

The dimeric ligands were constructed around spacers that were equipped with a primary amine on one end and an azide on the other end to allow orthogonal coupling to the appropriately derivatized dopamine and mGluR5 ligands, respectively (Figure 1).

Figure 1. Construction of the heterobivalent ligands.

As D₂R ligands we selected the 5-hydroxy-2-(dipropylamino)tetralin (5-OH-DPAT)[29] and the 1,4-disubstituted aromatic piperazine (1,4-DAPs)[30] that were equipped with an alkyne ligation handle to afford **3.07** and **3.03**, which may be swiftly connected to the azide group of the spacer via a copper-catalyzed azide–alkyne cycloaddition (CuAAC) reaction (Figure 2).

5-OH-DPAT is a prototypical D₂R/D₃R agonist suitable for constructing bivalent ligands.[31] Site directed mutagenesis has demonstrated that the 2-aminotetralin moiety interacts with an agonist binding domain involving TM3 and TM5 for activation of either D₂R or D₃R. The basic nitrogen and the 5-OH group are critical for binding affinity.

The intrinsic activity of 1,4-DAPs for D₂R originates from the aromatic head group and the amine moiety that forms a strong hydrogen bond with Asp^{3.32}. A lipophilic appendage enhances affinity. Because proper elongation of this appendage is expected to lead to the “entrance region” of the receptor and from there reaching out to the binding pocket of the neighboring protomer, the para-position of the benzylic appendage is considered an appropriate attachment point for a linker unit.[30]

As mGluR5 ligand we opted for the selective and potent mGluR5 NAM 3-[(2-methyl-4-thiazolyl)ethynyl]pyridine (MTEP).[5] MTEP analogues substituted at the 5-position of the 3-pyridyl moiety have been demonstrated to be more potent mGluR5 NAMs than those modified at the 2- or 6-positions.[23] Hence, we introduced a carboxylic acid at the 5-position of the 3-pyridyl moiety to afford

two carboxylic acid analogues of MTEP **4.01a-b** which are amenable for coupling to the amine group of the bifunctional spacers.

4.04b: n=4

Figure 2. Overview of appropriately modified monovalent ligands (parent ligands in red) and linkers used in this study. Parent ligands are indicated in red.

To construct the desired bivalent ligands, we considered three types of linkers with an azido group on one and an amino group on the other end, as to allow swift conjugation to alkyne modified dopamine ligands **3.07** and **3.03**, and the carboxylic acid containing MTEP analogues **4.01a-b**, respectively (Figure 2).

The first linker **4.02** is composed of a simple bifunctional hexamethylene chain. The polyethylene glycol (PEG) linkers **4.03a-b** were previously used to construct bivalent D₂R-μOR ligands.[29] These two classes of linkers have been frequently employed to compose bivalent ligands.[28],[30],[31],[32]

They allow to gradually increase spacer length. However, bivalent ligands involving such linkers resulted in a significant drop in binding affinity for D₄R. In a third type of linkers **4.04a-b**, we decided to introduce a protonatable nitrogen atom near the middle of the bifunctional polymethylene chain to reduce incremental increase in hydrophobicity upon elongation, which may result in aggregation in aqueous media.

IV.3.2. Synthesis

The alkyne functionalized D₂R ligands **3.07** and **3.03** were prepared as described earlier.[26],[29],[30] The synthesis of the MTEP derivatives equipped with a carboxylic acid handle started from thiazole **4.06**, which was obtained from 2-chloro acetyl chloride (**4.05**) in 2 steps following published procedures.[5],[23] Esters **4.08a-b** were obtained upon treatment of phenols **4.07a-b** with ethyl bromoacetate,[33],[34] and coupled with thiazole **4.06** in the presence of Pd(PPh₃)₂Cl₂ to furnish **4.09a-b**, respectively. Saponification of **4.09a-b** yielded carboxylic acids **4.01a-b**.

Scheme 1. Synthesis of Carboxylic Acid Modified MTEP Analogues **4.01a** and **4.01b**.

Reagents and conditions: i) Pd(PPh₃)₂Cl₂, CuI, TBAF, Et₃N, DMF, 85 °C, 2 h; ii) aq. NaOH.

Earlier procedures were followed for the preparation of the bifunctional polymethylene linker **4.02**,[35],[36] and the PEG linkers **4.03a-b**. [37]

Scheme 2. Synthesis of Orthogonally Functionalized Linkers **4.04a** and **4.04b**.

Reagents and conditions: i) NaBH(OAc)₃, CH₂Cl₂; ii) TFA, CH₂Cl₂.

Compound **4.11** was synthesized from the commercially available *N*-methylcaprolactam (**4.10**) in 4 steps.[38],[39],[40] Aldehydes **4.13a-b** were obtained from **4.12a-b** in 2 steps following the existing protocols.[41] Reductive amination **4.13a-b** with **4.11** using NaBH(OAc)₃ yielded **4.14a-b**, which, after Boc-deprotection with TFA, afforded the desired linkers **4.04a-b**.

The bivalent ligands were generated by first coupling the mGluR5 ligands with the different spacers using EDC and triethylamine to yield the seven intermediate azides **4.15**, **4.17a-b** and **4.19a-d**, which were subsequently conjugated with the DPAT- and DAP-alkynes through CuAAC (Scheme 3), leading to a series of nine bivalent D₂R-mGluR5 ligands.

Scheme 3. Synthesis of the Target Bivalent Ligands **4.16**, **4.18a-b**, **4.20a-b** and **4.21a-d**.

Reagents and conditions: i) (3-dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride, 1-hydroxybenzotriazole, triethylamine, CH_2Cl_2 ; ii) sodium ascorbate, CuSO_4 , triethylamine, tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine, dimethylformamide.

IV.3.3. Pharmacological evaluation

IV.3.3.1 Affinity of the bivalent ligands for the D₂R

A competition assay was performed to evaluate the binding affinity of the bivalent ligands for the D₂R (Table 1). First, the affinity of nine bivalent ligands along with the alkynylated precursors of DPAT (**3.07**) and DAP (**3.03**) was measured by displacement of [³H]raclopride from the D₂R expressed in HEK 293T cells. Raclopride is a selective D₂R antagonist that due to its more pronounced hydrophilic character shows substantially less non-specific binding than spiperone.[29] All bivalent ligands retained good to moderate affinity for the D₂R (Table 1). Similar observations were made in stably D₄R expressing HEK293 cells (supporting information). The DPAT-based ligand **4.20a**, featuring a type 3 linker consisting of 20 atoms showed the best affinity (50 ± 6.4 nM) for D₂R. Interestingly, amongst the

DAP-based ligands compound **4.21a** and **4.21c**, featuring the same spacer as **4.20a**, displayed the lowest K_i value (132 nM and 147 nM, respectively). A significant reduction (5- to 17-fold) in D₂R binding affinities was observed for the bivalent ligands with hexamethylene and PEG linkers.

Table 1. Binding affinities (K_i) for D₂R and D₂R-mGluR5.

Compd	X	R	Linker	K_i (nM) for D ₂ R	K_i (nM) for D ₂ R-mGluR5
3.07	-	-	-	17 ± 2.6	19 ± 1.8
3.03	-	-	-	77 ± 6.8	69 ± 22
4.16	N	DPAT	-OCH ₂ CONH (CH ₂) ₆ -	295 ± 99	142 ± 10
4.20a	N	DPAT	-OCH ₂ CONH(CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	50 ± 6.4	13 ± 3.6*
4.20b	N	DPAT	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	79 ± 16	171 ± 12
4.21a	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	132 ± 44	45 ± 5.3*
4.21b	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	303 ± 43	115 ± 32
4.21c	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	147 ± 24	94 ± 21
4.21d	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	398 ± 100	252 ± 54
4.18a	CH	DAP	-OCH ₂ CONH-PEG ₄ -	438 ± 89	251 ± 42
4.18b	CH	DAP	-OCH ₂ CONH-PEG ₆ -	352 ± 94	186 ± 75

Binding affinities (K_i) obtained by competitive displacement of [³H]raclopride from HEK293T D₂R and HEK293T D₂R-mGluR5 cell membranes. All values are expressed as the mean ± SEM of three independent assays. The affinity of bivalent ligands in the cells coexpressing D₂R and mGluR5 is significantly different (* p <0.05) compared to the cells monoexpressing D₂R.

Next, we determined the affinity of nine bivalent ligands and their corresponding alkyne precursors **3.07** and **3.03** for D₂R in the presence of overexpressed mGluR5. Interestingly, the affinity of **4.20a** to cells expressing both D₂R and mGluR5 (13 ± 3.6 nM) increased 4-fold compared to cells expressing

only D₂R (50 ± 6.4 nM). Likewise, the D₂R affinity of the DAP-containing bivalent ligand **4.21a** was 3-fold higher in cells co-expressing the mGluR5 (45 ± 5.3 nM versus 132 ± 44 nM). Furthermore, **4.20a** showed moderately higher affinity than **3.07** (19 ± 1.8 nM) and 10-fold higher affinity compared to the two other DPAT-based bivalent ligands **4.16** and **4.20b** in D₂R and mGluR5 co-expressing cells. All these data indicate that bivalent ligands **4.20a** and **4.21a** possibly bridge the binding sites of the D₂R and mGluR5 heterodimers. Furthermore, DPAT-based compound **4.16** containing a short hexamethylene linker showed a lower affinity for D₂R-mGluR5 relative to **4.20a** probably because its linker is too short to bridge the binding sites of the heterodimer. The preference for a tertiary amine linker as deduced from the superior affinities of **4.20a** and **4.21a** in the coexpressing cells may be partly due the H-bond that is formed between the tertiary amine group and D400 located on extracellular loop 3 (ECL3) of D₂R (see Computational modeling part below), which may compensate for the entropic penalty of the flexible linker. Based on the above results, a type 3 linker of appropriate length is preferred in this study.

These data indicate that bivalent ligands **4.20a** and **4.21a** possibly bridge the binding sites of the D₂R and mGluR5 heterodimers.

IV.3.3.2 Affinity of the bivalent ligands for the mGluR5

Competitive receptor binding assays in cell membranes from mGluR5 expressing cells allowed to determine the affinity for said receptor using [³H]MPEP, a nonselective mGluR5 antagonist. Results of saturation binding assays for [³H]MPEP can be found in supporting information. The binding affinities of the azido precursor **4.19a** for mGluR5 and D₂R-mGluR5 were 5.8 ± 0.9 μ M and 5.7 ± 0.8 μ M, respectively (Table 2). In addition, the affinity of **4.01a** for mGluR5 was 6.5 ± 0.6 μ M, which is comparable to that of **4.19a**. This led us to use **4.19a** as control in ligand binding and further functional assays for mGluR5.

Bivalent ligand **4.20a** showed a 2-fold gain in binding affinity in cells expressing both D₂R and mGluR5 compared to cells solely expressing mGluR5. Interestingly, **4.20a** exhibited a 5-fold higher affinity (1.1 ± 0.2 μ M) for D₂R-mGluR5 compared to its azido precursor **4.19a** lacking a D₂R ligand (5.7 ± 0.8 μ M). Likewise, **4.21a** displayed 4-fold higher affinity (1.3 ± 0.2 μ M) for D₂R-mGluR5 relative to **4.19a**. All these results indicate that bivalent ligands **4.20a** and **4.21a** bridge the orthosteric and allosteric binding sites of the D₂R and mGluR5 heteromer, respectively.

Table 2. Binding affinities (K_i) for mGluR5 and mGluR5-D₂R.

Entry	X	R	Linker	K_i (μ M) for mGluR5	K_i (μ M) for D ₂ R-mGluR5

4.21a	N	DAP	-OCH ₂ CONH(CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	1.0 ± 0.3	1.3 ± 0.2*

Binding affinities (K_i) obtained by competitive displacement of [³H]MPEP from HEK293T cell membranes expressing mGluR5 and D₂R-mGluR5. All values are expressed as the mean ± SEM of three independent assays performed in duplicate. The affinity of bivalent ligands is significantly different (* p <0.05) compared to that of monovalent ligand in the cells coexpressing D₂R and mGluR5.

IV.3.3.3 D₂-likeR activation (MAPK phosphorylation) by the bivalent ligands

The mitogen-activated protein kinase (MAPK) phosphorylation assay was used to assess the efficiency of the bivalent ligands. The MAPK pathway, also known as the extracellular-signal regulated kinase (ERK) pathway, consists of an intracellular chain of proteins that transfer the signal from the transmembrane receptor to the nuclear DNA or other subcellular targets via transfer of phosphate groups and functions as an “on/off” switch.[42] The most commonly studied step of the MAPK pathway, initiated by GPCR activation, is the phosphorylation of p44/42 MAPK (ERK1/2).

In a previous study we demonstrated that D₂-likeR ligands based on DAP-alkyne and DPAT-alkyne caused stronger MAPK phosphorylation in D₄R-expressing than in D₂R-expressing cells.[29] To assess functional activation of the D₂-likeR by our bivalent ligands, we therefore used HEK293 cell lines stably expressing either D₄R or D₂R and mGluR5 (Figure 3 and Table 3).[43] All bivalent ligands were found to activate the MAPK signaling pathway in cells expressing the D₄R (Figure 3), with a potency that is comparable or slightly weaker than that of alkyne precursors **3.07** and **3.03** (Table 3). Interestingly, compound **4.20a** was slightly more potent (EC_{50} = 0.28 ± 0.03 μM) than alkyne derived DPAT (**1**) (EC_{50} = 0.37 ± 0.17 μM), while the potency of the DPAT derivatives with shorter (**4.16**) and longer linkers (**4.20b**) decreases 3- and 5-fold. Similarly, ligand **4.21a** was slightly more potent (0.8 ± 0.1 μM) than the other DAP-based bivalent ligands (EC_{50} = 1.1-2.7 μM).

Next, we performed MAPK phosphorylation to test bivalent ligands **4.20a**, **4.21a** and their corresponding alkyne precursors **3.07** and **3.03** in a stable cell line coexpressing D₂R and mGluR5 (Table 3 and supporting information). Unexpectedly, only bivalent ligand **4.20a** gave a stronger MAPK-P band than the control serum-free media (SFM). It displayed 4-fold higher potency (0.021 ± 0.009 μM) than **3.07** (0.078 ± 0.007 μM). On the other hand, **4.21a** and **3.03** gave weaker MAPK-P signal bands than SFM, indicative for D₂R antagonist properties for DAP-alkyne based ligands (supporting information).

Figure 3. Efficacy of bivalent ligands to phosphorylate MAPK in HEK293 D₄R cells. Cells were treated with serum-free media (SFM) for 12 h. Next, D₂R agonists (10 μ M) and SFM were added for 5 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Cells treated with SFM served as control. The top panel shows a representative result from three independent experiments; the bottom panel is given as mean \pm SD. DA=dopamine. Bivalent ligands were significantly different (* p < 0.05, ** p < 0.01, *** p < 0.001) compared to the control SFM by One-way ANOVA.

IV.3.3.4 cAMP assay to study intrinsic activities of the selected D₂R ligands.

To further understand the intrinsic activities of the selected bivalent ligands **4.20a** and **4.21a** and their corresponding monovalent ligands **3.07** and **3.03** comprising the pharmacophore of a D₂R agonist and a D₂R antagonist, respectively, we performed a bioluminescence based cAMP accumulation assay (Figure 4 and Table 4).[44] Coupled to inhibitory G $\alpha_{i/o}$ proteins, activation of the D₂R decreases cAMP production.

Similar to the reference D₂R agonist quinpirole, bivalent ligands **4.16**, **4.20a**, **4.20b** and its alkyne precursor **3.07** inhibited forskolin-induced cAMP accumulation both in cells monoexpressing D₂R or in cells coexpressing D₂R and mGluR5. Interestingly, in the latter cells a significantly lower EC₅₀ value was observed for bivalent ligand **4.20a** (EC₅₀ = 1.5 ± 0.5 nM) compared to **3.07** (EC₅₀ = 6.5 ± 0.6 nM), indicating that the bivalent binding requires a lower receptor occupation to exert signaling. However, **4.16** and **4.20b** exhibited 3- and 5-fold lower potencies (20 nM and 32 nM, respectively) in the coexpressing cell line relative to **3.07**, revealing weak D₂R agonism. In D₂R/mGluR5-coexpressing cells, quinpirole and the monovalent D₂R agonist **3.07** inhibited cAMP formation with similar potencies as in cells monoexpressing D₂R, while **4.20a** decreased cAMP production with a 2-fold higher potency in the coexpressing cells than in monoexpressing D₂R cells. Nevertheless, **4.16** and **4.20b** displayed 2- and 6-fold lower potencies in the coexpressing cells than in the monoexpressing cells.

Consistent with the MAPK-P results, bivalent ligand **4.21a** and its alkyne precursor **3.03** failed to inhibit cAMP accumulation (Figure 4) both in the D₂R solely expressed cells and in the D₂R/mGluR5 coexpressed cells, suggesting that DAP-based bivalent ligands show D₂R antagonist behavior, which is in line with the reported results.[30]

Figure 4. Dose-response curves of cAMP accumulation for representative ligands. Functional activity of selected bivalent ligands and its precursor **3.03** and **3.07** determined in HEK 293T cells stably expressing the D₂R (a) or both D₂R and mGluR5 (b) and coexpressing the pGloSensor-22F cAMP plasmid via transient transfection. Cells were stimulated with increasing amounts of the ligands (0.1 nM–10 μ M) in the presence of 10 μ M forskolin. cAMP production was normalized to the percentage of forskolin-induced cAMP concentration (100%). Data represent mean \pm SD of three independent experiments each performed in duplicate.

Table 4. Potency of inhibition of forskolin mediated cAMP accumulation for bivalent ligands based on D₂R agonist DPAT-alkyne.

Data shown represent the mean \pm SEM of three independent experiments.

IV.3.3.5 MAPK phosphorylation to study the potency of the newly developed bivalent ligands for mGluR5

It is well known that activation of mGluR5 by its agonist (*S*)-3,5-dihydroxyphenylglycine (DHPG) leads to phosphorylation of MAPK in HepG2 cells.[45] Here, we examined the MAPK-P in response to L-glutamic acid (L-Glu) and (*R,S*)-2-chloro-5-hydroxyphenylglycine (CHPG) treatment in HEK293 mGluR5 and HEK293 mGluR5-D₂R stable cell lines (supporting information). The results showed that MAPK-P peaked at approximately 10 min for mGluR5 and 7-10 min for mGluR5-D₂R after 10 μ M L-Glu treatment. To assess the inhibition of MAPK phosphorylation by the bivalent ligands, cells were pretreated with **4.19a** and all bivalent ligands for 30 min before incubation of the cells for 10 min with L-Glu (10 μ M). All bivalent ligands proved capable of inhibiting MAPK-P activated by L-Glu (supporting information).

To assess their potency we tested all bivalent ligands and azido precursor **4.19a** (1 nM-10 μ M) in HEK 293 mGluR5 cells (Table 5) and selected compounds **4.19a**, **4.20a** and **4.21a** in HEK 293 mGluR5-D₂R cells (Table 5). Compound **4.20a** was more potent (0.17 ± 0.02 μ M) than the other DPAT-based bivalent ligands in blocking MAPK-P for mGluR5. DAP-based bivalent ligand **4.21a** featuring an identical linker as **4.20a** displayed a higher potency (0.11 ± 0.05 μ M) than the other DAP-bond ligands in the cells monoexpressing the mGluR5. In addition, DAP-based bivalent ligands with PEG linkers showed lower antagonistic activity compared to DAP-based ligands with a tertiary amine linker.

Interestingly, bivalent ligands **4.20a** and **4.21a** exhibited 7- and 2-fold higher potency ($IC_{50} = 0.62$ μ M and 1.8 μ M) in mGluR5-D₂R compared with their monovalent precursor **4.19a** ($IC_{50} = 4.5$ μ M).

Table 5. Potency (IC_{50}) of mGluR5 antagonists blocking MAPK-P activated by L-Glu (10 μ M) in HEK293 mGluR5 and HEK293 mGluR5-D₂R stable cell lines.

IV.3.3.6 Computational modeling of a bivalent ligand bound to an mGluR5-D₂R heterodimer

The binding pose of compound **4.20a** was investigated *in silico* through protein-protein docking of crystal structures: transmembrane domains (TMD) of mGluR5 and D₂R, followed by docking of the bivalent ligand into the modeled heterodimer (see Experimental Section). As both receptors are co-crystallized with either negative allosteric modulator (NAM)[46] or antagonist,[47] they can be considered to be in their respective inactive states. As the bivalent ligand **4.20a** is a fusion of mGluR5 NAM and D₂R agonist, this means mGluR5 is in an ideal conformation but not D₂R, which would theoretically be active in such a heterodimer-ligand complex. Furthermore, as the original crystal structure of mGluR5 has no clear entrance or exit for NAMs because of its tightly closed extracellular loops and TMD,[46] a modified conformation of the receptor was deemed necessary to correctly bind a bivalent compound. Such a conformation has been observed previously, firstly with a Monte Carlo sampling technique employed for the purposes of docking photo-sensitive[48] and long linear[49] mGluR5 NAMs, and secondly during molecular dynamics (MD) simulations of mGluR5 with bound NAM.[50] In summary, this alternative mGluR5 conformation is in an inactive state and similar to the original mGluR5 crystal structure[46] but undergoes a partial separation of the extracellular ends of TM5 and TM6, which are highly flexible.[50] This potentially allows NAMs to enter or leave and is conducive for the linker of a bivalent ligand to pass outside of the receptor. As such, we utilized this MD-generated mGluR5 conformation[50] for modeling interactions with D₂R, whose crystal structure has no such limitations regarding the binding of a bivalent ligand.

In terms of modeling an mGluR5-D₂R heterodimer, referring to experimental information is important as these proteins can potentially interact in a number of ways. Interestingly, TM5 and TM6 have been experimentally observed to dynamically participate in the interface(s) of an mGluR2 homodimer,[51] as well as TM5 involved in cross-talk between mGluR2 and the Class A GPCR, 5-HT_{2A} receptor.[52],[53],[54] Based on homology between mGluR2 and mGluR5 TMDs (sequence identity of 51%), physical interaction between mGluR5 and D₂R may follow a similar pattern. In addition,

participation of mGluR5 TM5 and/or TM6 in a direct interaction with D₂R would provide a means of passing a bivalent ligand between receptors. Likewise for D₂R, TM5 and TM6 have been observed to participate in its experimentally characterized homodimeric and heteromeric receptor interactions.[55],[56],[57],[58] As such, we modeled an mGluR5-D₂R heterodimer via its respective TM5-TM6 helices by using the mu-opioid homodimer crystal structure as a template,[59] which contains an analogous interface. This initial mGluR5-D₂R model was refined with protein-protein docking to identify an optimal interaction between the receptors (see Experimental Section). The best docked mGluR5-D₂R conformation results in close packing of residues at the TM5-TM6 interface (Figure 5B). However, as D₂R is in an inactive state with its TM6 in an inward rather than outward orientation,[47] the contact surface between receptors is possibly not as extensive as it could be. Nevertheless, the reported docking score is respectable, suggesting a favorable interaction (I_{sc} of -6.6 on a scale of 0 to -10, where better than -5 is considered satisfactory[60]).

Compound **4.20a** was bound to the mGluR5-D₂R heterodimer model by first, automatically docking its separate mGluR5 NAM (MTEP) and D₂R agonist (DPAT-alkyne, **1**) components, second, by manually connecting these with the appropriate linker, and third, energy minimizing the resulting complex (see Experimental Section). It was found that by following this process, **4.20a** is able to simultaneously bind both receptors, passing between TM5 and TM6 of each (Figure 5A) with the linker residing at the membrane surface or just beneath (Figure 5B). In the modeled complex, compound **22a** is able to make six protein-ligand H-bonds: two with mGluR5 and four with D₂R (Figure 4C). In mGluR5, these H-bonds involve residues S805 and S809 on TM7, both of which interact with the MTEP component of **4.20a** (Figure 5C). These observed protein-ligand H-bonds are consistent with known mGluR5 NAM binding modes previously identified in mGluR5 crystal structures,[46],[61] and published mGluR5 MD simulations.[48],[50] In D₂R, the DPAT component of **4.20a** makes an H-bond with D114 on TM3 in the same manner as co-crystallized risperidone in the original D₂R crystal structure.[47] However, in line with its potential D₂R agonism and unlike risperidone, **4.20a** makes additional H-bonds with the backbone oxygen of S193 on TM5 and Y408 hydroxyl group on TM7 (Figure 5C). The importance of S193 for the binding of D₂R agonists has been noted before,[62] along with neighboring residues, S194 and S197. Due to the closeness of these three particular serine residues in the D₂R crystal structure, only moderate conformational changes in TM5 (due to receptor activation, for example) would be required for **4.20a** to make H-bonds with the sidechain hydroxyl groups of either S193, S194 or S197. Finally, the tertiary amine on the linker of **4.20a** makes an H-bond with D400 located on extracellular loop 3 (ECL3) of D₂R (Figure 5C). This interaction is likely conducive to the conformational stability of this particular linker, which might otherwise (e.g. PEG-linkers) become a destabilizing factor.

Overall, due to the number of observed protein-ligand H-bonds with both receptors, as well as consistency with known mGluR5 and D₂R ligand binding modes, the modeled heterodimer-ligand complex appears to be compatible with the reported biological activity of compound **4.20a**.

Figure 5. The modeled mGluR5-D₂R-compound 4.20a complex. A) Extracellular top-view of the interaction between mGluR5 (blue ribbon, derived from PDB id: 4009) and D₂R (green ribbon, PDB id: 6CM4) via symmetrical TM5-TM6 interface, including bound compound **4.20a** (carbons as pink spheres). B) Side-view of mGluR5-D₂R heterodimer with bound **4.20a** (carbon, nitrogen, oxygen and sulphur atoms as pink, dark blue, red and yellow spheres, respectively), showing contact interface (carbons as blue and green spheres, respectively) within a model membrane (red dots and blue lines, representing upper and lower leaflets, respectively). C) Modeled binding mode of compound **4.20a** (pink) within respective allosteric and orthosteric pockets of mGluR5-D₂R heterodimer (blue and green ribbons, respectively). Protein-ligand H-bonds are displayed as solid black lines (S805 is partially obscured by the ligand). Selected residues on mGluR5: TM6, TM7 and D₂R: TM3, TM5, TM7 and ECL3 are displayed (mGluR5: TM3, TM5 and D₂R: TM6 are transparent for visualization purposes).

IV.4. Conclusion

In summary, we have designed and synthesized nine potential heterobivalent ligands based on the chemical structure of two distinct D₂-likeR agonist/antagonist and two mGluR5 NAMs. Ligation of D₂-likeR ligands shows that bivalent ligands with PEG (PEG₄ and PEG₆) and hexamethylene linkers exhibit relatively low affinity for D₂R and D₄R, contrary to bivalent ligands with alkylamine spacers, while all

can still activate MAPK phosphorylation in D₂R cells. Interestingly, bivalent ligand **4.20a**, with a 20-atom alkylamine spacer, showed a 4-fold affinity increase for the D₂R in cells expressing both the D₂R and the mGluR5, compared to cells only expressing D₂R, suggesting that **4.20a** may bridge the binding sites of the D₂R and mGluR5 receptors. Moreover, **4.20a** shows a 5-fold higher affinity for the mGluR5 than its MTEP azido precursor **4.19a** in D₂R-mGluR5 cells, also pointing towards its capacity to simultaneously occupy both binding sites of the heteromer. From a functional point of view, **4.20a** displays 4- and 7-fold higher potency compared to the monomeric precursors **3.07** and **4.19a** in MAPK phosphorylation, respectively, in cell lines stably expressing D₂R and mGluR5 receptors. Moreover, **4.20a** inhibits forskolin stimulated cAMP formation with a 4-fold higher potency compared to alkyne **3.07** in the coexpressing cells, indicating that the bivalent binding requires a lower receptor occupation to exert signaling. In addition, a docking study reveals that **4.20a** is indeed able to simultaneously bind both receptors by passing between the heterodimeric interface, comprised of TM5 and TM6 of both receptors, and establishing six protein-ligand H-bonds.

Overall, we demonstrated that the length and composition of the linker between the two receptor pharmacophores strongly affect binding affinity and functional potency both from a D₂R and from a mGluR5 viewpoint. Most importantly, this study allowed to identify bivalent ligand **4.20a**, which emerges as a promising molecular probe to further investigate D₂R and mGluR5 heterodimerization.

IV.5. Experimental Section

IV.5.1. Chemistry

IV.5.1.1 General

All reactions described were performed under an N₂ atmosphere and at ambient temperature unless stated otherwise. All reagents and solvents were purchased from Sigma-Aldrich (Diegem, Belgium), Fisher Scientific (Merelbeke, Belgium), TCI Europe (Zwijndrecht, Belgium) or Apollo Scientific (Bredbury, Stockport, United Kingdom) and used as received. NMR solvents were acquired from Eurisotop (Saint-Aubin, France). Reactions were monitored by TLC analysis using TLC aluminium sheets (Macherey-Nagel, Alugram Sil G/UV254) with detection by spraying with a solution of (NH₄)₆Mo₇O₂₄·4H₂O (25 gL⁻¹) and (NH₄)₄Ce(SO₄)₄·2H₂O (10 gL⁻¹) in H₂SO₄ (10 % aq.) followed by charring or an aqueous solution of KMnO₇ (20 gL⁻¹) and K₂CO₃ (10 gL⁻¹) or an ethanolic solution of ninhydrin (2 gL⁻¹) and acetic acid (1% v/v) followed by charring. Solution pH values were estimated using universal indicator paper (Merck). Silica gel column chromatography was performed using a Grace Reveleris X2 system and the corresponding silica gel cartridges. ESI-HRMS spectra were measured with a Waters LCT Premier XE Mass spectrometer calibrated using leucine enkephalin as an external standard. ¹H- and ¹³C-APT-NMR spectra were recorded with a Varian Mercury-300BB (300/75

MHz) spectrometer. Chemical shifts are given in ppm (δ) relative to tetramethylsilane as an internal standard (^1H NMR) or the NMR solvent (^{13}C NMR). Coupling constants are given in Hertz (Hz). Weak signals in ^{13}C NMR are indicated as (w). LC-MS analyses were carried out on a Waters AutoPurification System equipped with PDA and ESI-MS detection and using a Waters CORTECS C18 Column (4.6 \times 100 mm, 2.7 μm) and a water/acetonitrile/formic acid linear gradient system at a flow rate of 1.44 mLmin $^{-1}$.

IV.5.1.2 General Procedure for the Carbodiimide-Mediated Amide Formation.

To a solution of (3-Dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride (1.5 eq.) and 1-hydroxybenzotriazole (1.4 eq.) in CH_2Cl_2 was added a solution of the PEG spacer (1.2 eq.) in CH_2Cl_2 (0.2 M) and cooled to 0 $^\circ\text{C}$ under an argon atmosphere. After 15 min at 0 $^\circ\text{C}$, amines (1.0 eq.) were added and triethylamine (2 eq.) was added dropwise; the reaction was slowly warmed to room temperature and stirred overnight. The reaction was diluted with CH_2Cl_2 , washed successively with water, HCl (5% aq.), NaHCO_3 (sat. aq.), NaCl (sat. aq.), dried over Na_2SO_4 , filtered and solvent was evaporated under reduced pressure. The crude product was purified by silica gel chromatography ($\text{NH}_4\text{OH}/\text{MeOH}/\text{CH}_2\text{Cl}_2$, 1:5:94 v/v/v) to yield the amides.

IV.5.1.3 General Procedure for Copper Mediated Azide-Alkyne Cycloaddition.

To a solution of the intermediate azide (1.0 eq.) in dimethylformamide (0.1 M) was added the alkyne (1.5 eq.), sodium ascorbate (1.0 eq., 0.5 M), CuSO_4 (0.2 eq., 0.05 M), triethylamine (3.0 eq.) and a catalytic amount of tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine. The reaction mixture was stirred overnight at room temperature in the dark under an argon atmosphere. The solvent was evaporated under reduced pressure and the residue was redissolved in water and extracted with CH_2Cl_2 . Then combined organic fractions were pooled, washed with brine and dried over Na_2SO_4 . The crude compound was purified by silica gel chromatography ($\text{NH}_4\text{OH}/\text{MeOH}/\text{CH}_2\text{Cl}_2$, 1:5:94 v/v/v) to give the final compound as a white solid.

Ethyl 2-((5-((2-methylthiazol-4-yl)ethynyl)pyridin-3-yl)oxy)acetate (4.09a). To a solution of compound **4.06** (1.95 g, 10 mmol) in DMF was added esters **4.08a** (2.8 g, 11 mmol), CuI (190 mg, 1 mmol) and triethylamine (2.1 mL, 15 mmol). $\text{Pd}(\text{PPh}_3)_2\text{Cl}_2$ (350 mg, 0.5 mmol) was added to the reaction solution and the argon flow was continued for 10 min to remove air. Then a solution of TBAF (11 mmol, 1.0 M in THF) was added dropwise over 30 min. The mixture was heated at 85 $^\circ\text{C}$ for 1 h. After reaction, the mixture was filtrated and concentrated under reduced pressure. The residue was purified by silica gel chromatography (Hexane/EtOAc, 3:1-1:1 v/v) to yield compound **4.09a** as a brown solid (1.82 g, 60.2%). ^1H NMR (300 MHz, CDCl_3) δ ppm 8.43 (d, J = 1.6, 1H), 8.30 (d, J = 2.9 Hz, 1H), 7.42 (s, 1H), 7.30 (dd, J = 2.9, 1.6 Hz, 1H), 4.65 (s, 2H), 4.28 (q, J = 7.1 Hz, 2H), 2.74 (s, 3H), 1.30 (t, J = 7.1 Hz,

3H). ^{13}C NMR (75 MHz, CDCl_3) δ 167.8, 166.0, 153.4, 145.6, 138.2, 136.1, 123.2 (d, $J=4.5$ Hz), 119.9, 86.7, 85.0, 65.4, 61.7, 19.2, 14.1. HRMS (ESI) m/z : calculated for $\text{C}_{15}\text{H}_{15}\text{N}_2\text{O}_3\text{S}$ $[\text{M}+\text{H}]^+$ 303.0803; found 303.0807.

Ethyl 2-(3-((2-methylthiazol-4-yl)ethynyl)phenoxy)acetate (4.09b). Compound **4.09b** was prepared using the procedure described as **4.09a**. Yellow oil (3.88 g, 64%). ^1H NMR (300 MHz, CDCl_3) δ ppm 7.36 (s, 1H), 7.28 – 7.22 (m, 1H), 7.18 (dt, $J=7.6, 1.3$, 1H), 7.07 – 7.04 (m, 1H), 6.95 – 6.90 (m, 1H), 4.61 (s, 2H), 4.27 (q, $J=7.1$ Hz, 2H), 2.73 (s, 3H), 1.29 (t, $J=7.2$ Hz, 3H). ^{13}C NMR (75 MHz, CDCl_3) δ ppm 168.5, 165.6, 157.5, 136.7, 129.5, 125.3, 123.6, 122.3, 117.0, 116.0, 88.3, 83.4, 65.3, 61.4, 19.2, 14.1. HRMS (ESI) m/z : calculated for $\text{C}_{16}\text{H}_{16}\text{NO}_3\text{S}$ $[\text{M}+\text{H}]^+$ 302.0851; found 302.0850.

2-((5-((2-Methylthiazol-4-yl)ethynyl)pyridin-3-yl)oxy)acetic acid (4.01a). To a solution of ester **4.09a** (2.3 g, 7.6 mmol) in methanol was added 4 M NaOH (38 mmol, aq.) and then stirred at room temperature for 2 h. Then 1 M HCl (aq.) was added to the solution to acidify it till pH=2. Next the solvent was removed under reduced pressure and the residue was purified by silica gel chromatography (AcOH/Hexane/EtOAc 1:49:50 v/v/v) to yield acid **4.01a** as a pale yellow solid (1.8 g, 86%). ^1H NMR (300 MHz, $\text{DMSO}-d_6$) δ ppm 12.37 (br s., 1H), 8.29 (br s, 2H), 7.90 (s, 1H), 7.52 (s, 1H), 4.82 (s, 2H), 2.63 (s, 3H). ^{13}C NMR (75 MHz, $\text{DMSO}-d_6$) δ ppm 172.4, 166.3, 151.6, 144.4, 138.8, 135.2, 125.6, 123.1, 119.1, 87.4, 85.1, 65.1, 19.0. HRMS (ESI) m/z : calculated for $\text{C}_{13}\text{H}_{11}\text{N}_2\text{O}_3\text{S}$ $[\text{M}+\text{H}]^+$ 275.0490; found 275.0478.

2-(3-((2-Methylthiazol-4-yl)ethynyl)phenoxy)acetic acid (4.01b). Compound **4.01b** was prepared using the procedure described as **4.01a**. Pale yellow solid (2.5 g, 82%). ^1H NMR (300 MHz, $\text{DMSO}-d_6$) δ ppm 12.88 (br s., 1H), 7.88 (s, 1H), 7.32 (t, $J=8.4$ Hz, 1H), 7.14 – 7.09 (m, 1H), 7.03 (dt, $J=2.5, 0.9$ Hz, 1H), 6.98 (ddd, $J=8.3, 2.7, 1.0$ Hz, 1H), 4.71 (s, 2H), 2.64 (s, 3H). ^{13}C NMR (75 MHz, $\text{DMSO}-d_6$) δ 170.4, 166.1, 158.1, 135.7, 130.4, 124.9, 124.6, 123.0, 117.0, 116.5, 88.2, 84.4, 64.9, 19.1. HRMS (ESI) m/z : calculated for $\text{C}_{14}\text{H}_{12}\text{NO}_3\text{S}$ $[\text{M}+\text{H}]^+$ 274.0538; found 274.0544.

***tert*-Butyl (5-((8-azidooctyl)(methyl)amino)pentyl)carbamate (4.14a).** To a solution of **4.13a** (1.7 g, 10 mmol) in CH_2Cl_2 (50 ml) was added the compound **4.11** (2.4 g, 11 mmol) and $\text{Na}(\text{OAc})_3\text{BH}$ (4.2 g, 20 mmol) and stirred at room temperature for 6 h. The mixture was quenched by NaHCO_3 (sat.) and extracted with CH_2Cl_2 (3x 50 ml), washed with brine and dried over Na_2SO_4 . The mixture was filtered and concentrated under reduced pressure. The crude was purified by silica gel chromatography (MeOH/ CH_2Cl_2 5:95 v/v) to yield **4.14a** as a colorless oil (2.3 g, 62%). ^1H NMR (300 MHz, CDCl_3) δ 4.65 (s, 1H), 3.22 (t, $J=6.9$, 2H), 3.08 (q, $J=6.4$ Hz, 2H), 2.74 – 2.63 (m, 4H), 2.50 (s, 3H), 1.73 – 1.43 (m, 6H), 1.40 (s, 9H), 1.36 – 1.23 (m, 12H). ^{13}C NMR (75 MHz, CDCl_3) δ 156.1, 80.6, 56.2, 51.3, 45.6, 40.3, 29.6, 29.0, 28.9, 28.7, 28.3, 26.9, 26.5, 24.6, 24.3, 24.1. HRMS (ESI) m/z : calculated for $\text{C}_{19}\text{H}_{40}\text{N}_5\text{O}_2$ $[\text{M}+\text{H}]^+$ 370.3182; found 370.3175.

***tert*-Butyl (5-((10-azidodecyl)(methyl)amino)pentyl)carbamate (4.14b).** Compound **4.14b** was obtained according to the procedure described for compound **4.14a**. Colorless oil (3.3 g, 83%). ¹H NMR (300 MHz, CDCl₃) δ 4.62 (s, 1H), 3.23 (t, *J* = 6.9 Hz, 2H), 3.08 (q, *J* = 6.6 Hz, 2H), 2.64 – 2.52 (m, 4H), 2.41 (s, 3H), 1.68 – 1.43 (m, 6H), 1.41 (s, 9H), 1.38 – 1.20 (m, 16H). ¹³C NMR (75 MHz, CDCl₃) δ 156.0, 79.4, 56.5 (d, *J* = 16.0 Hz), 51.4, 45.6, 40.8, 40.2, 29.6, 29.2 (d, *J* = 5.1 Hz), 29.1, 28.7, 28.3, 27.1, 26.6, 25.1 (d, *J* = 25.6 Hz), 24.3. IV.5.2. Generation of the stable D2s-mGluR5 co-expressing cell line

Production of the stable D2s-mGluR5 co-expressing cell line was conducted by a retroviral transduction of D2s (human) into the *mGluR5a-HEK293-TREx* stable cell line (a kind gift of Janssen Pharmaceutical Companies of Johnson & Johnson), stably transfected with the mGluR5a/pcDNA4-TO construct (RefSeq NM_000842; RefSeqP NP_000833).

The retroviral construct of D2s was generated by PCR-amplifying the D2s sequence (RefSeq NM_016574.3) flanked by the *SnaBI/NotI* restriction enzyme sites and cloned into the digested retroviral vector pLZRS-IRES-EGFP. The integrity of the insert was confirmed by DNA sequencing. The pLZRS-D2s-IRES-EGFP plasmid leads to co-expression of the D2s and eGFP, the latter can be used as a marker for cell sorting and to check the stability of the cell lines by flow cytometry.

For the production of retrovirus and retroviral transduction the Phoenix-Amphotropic packaging cell line[33] was used (a kind gift from prof. Bruno Verhasselt, Department of Clinical Chemistry, Microbiology, and Immunology, Ghent University, Belgium). The cells were transfected with LZRS-D2s-IRES-EGFP, by calcium phosphate precipitation (Invitrogen, San Diego, CA, USA). After puromycin selection of 2 weeks, the retroviral supernatant was harvested, spun down (10 min at $350 \times g$) and aliquots of the supernatant were stored at -80°C until use. For transduction of human embryonic kidney (HEK) 293T cells, 10^4 cells/well were seeded in a transparent 96-well plate. After 24 h, the medium was refreshed with the retroviral supernatant, which had been preincubated for 10 min with Dotap (Roche Diagnostics). To increase transduction efficiency, the plates were spun down (90 min, $950 \times g$, 32°C). Transduction efficiency was measured by flow cytometry 48 h after transduction, via assessment of expression of EGFP. Cell sorting was done on a BD FACSAria III, equipped with 405, 488, 561, and 640 nm lasers (BD Biosciences, Erembodegem, Belgium).

All cells were cultured at 37°C , 5% CO_2 , under humidified atmosphere in DMEM (high glucose) supplemented with 10% heat inactivated fetal bovine serum (FBS), 2 mM of glutamine, 100 IU/ml of penicillin, 100 $\mu\text{g}/\text{mL}$ of streptomycin, and 0.25 $\mu\text{g}/\text{mL}$ of amphotericin B. Stability of the cell line was followed up by flow cytometric analysis.

IV.5.3. Cell culture and transfection

Human embryonic kidney (HEK) 293T cells and HEK 293 mGluR5 cells (Janssen Pharmaceutica, Belgium) were cultured in Dulbecco's modified Eagle's medium (DMEM; Invitrogen), supplemented with 10% fetal bovine serum, penicillin (100 U/ml), and streptomycin (100 $\mu\text{g}/\text{mL}$) in a controlled environment (37°C , 98% humidity, 5% CO_2). For ligand binding experiments, HEK293T cells were transiently transfected using the Polyethylenimine (PEI) method as described before.[43],[63] A total amount of 10 μg of DNA was used for transfection of cells in one 10-cm dish. HEK293S cells stably

expressing HA D_{4.2}R[43] were grown in DMEM/F12 (Gibco, Invitrogen) supplemented with 10% fetal bovine serum, penicillin (100 U/ml), streptomycin (100 µg/ml), and 0.5 mg/ml G418 (Geneticin, Gibco) in a controlled environment (37 °C, 98% humidity, 5% CO₂).

IV.5.4. Membrane Preparation and Protein Determination.

Membrane suspensions from HEK293T cells transiently transfected with the receptors of interest were prepared as described previously.[29] Cells were disrupted with a Polytron homogenizer for two 10 s periods in 10 volumes of ice-cold Tris-HCl buffer (50 mM, pH 7.4). Membranes were obtained by centrifugation at 16500g for 20 min at 4 °C, and the pellet was resuspended and centrifuged under the same conditions. The resulting pellet was stored at -80 °C and was washed once more as described above and resuspended in Tris-HCl buffer (50 mM, pH 7.4) for immediate use. Protein was quantified by the BCA method using bovine serum albumin dilutions as the standard.

IV.5.5. [³H]Spiperone Binding.

Saturation binding assay for [³H]spiperone was performed as previously described.[64],[65] For competition binding assays, membranes (20 µg) were incubated in binding buffer (50 mM Tris-HCl containing 5 mM KCl, 1 mM EDTA, 1.5 mM CaCl₂ and 4 mM MgCl₂, pH 7.4) with 0.2 nM [³H]spiperone (specific activity = 76 Ci/mmol, PerkinElmer, USA) in the absence or presence of varying concentrations (0.1 nM-10 µM) of unlabeled ligands for 1 h at 22 °C. Nonspecific binding was determined in the presence of 1 µM haloperidol. Incubation was terminated by rapid filtration through GF/C glass-fiber filters (Whatman Schleicher and Schuell, Keene, NH) embedded in 0.1% polyethylenimine and mounted on a Brandel cell harvester. Filters were washed three times with cold 50 mM Tris-HCl, pH 7.4 buffer and transferred to vials containing 3 mL of scintillation cocktail to soak the filter overnight. The radioactivity counts were measured with a Tri-Carb 2800TR liquid scintillation analyzer (PerkinElmer).

IV.5.6. [³H]Raclopride Binding.

[³H]raclopride saturation binding assay was performed as described before.[66] Briefly, a suspension of whole cells or cell membranes (corresponding a total protein amount of 20 µg) were incubated with different concentrations (0–20 nM) of [³H]raclopride in 50 mM Tris-HCl, pH 7.4 buffer (containing 5 mM KCl, 100 mM NaCl, 1.5 mM CaCl₂, 4 mM MgCl₂ and 1 mM EDTA) at 37 °C for 1 h. For competitive binding experiments, 2.0 nM [³H]raclopride (specific activity = 73.8 Ci/mmol, PerkinElmer, USA) was incubated with 20 µg of cell membranes in the absence or presence of varying concentrations (0.1 nM-10 µM) of unlabeled ligands at 37 °C for 1 h. Nonspecific binding was determined in the presence of 1 µM haloperidol. Filtration and measuring were as described above.

IV.5.7. [³H]MPEP Binding.

[³H]MPEP saturation binding assay was adapted from a published protocol.[67] Membranes (20 µg) were incubated with different concentrations (0–10 nM) of [³H]MPEP in 50 mM Tris-HCl and 2 mM MgCl₂, pH 7.4 buffer at 25 °C for 1 h. For competitive binding experiments, 3.0 nM [³H]MPEP (specific activity = 60 Ci/mmol, American Radiolabeled Chemicals, Inc.) was incubated with 20 µg of membranes in the absence or presence of varying concentrations (0.1 nM-100 µM) of unlabeled ligands at 25 °C for 1 h. Nonspecific binding was determined in the presence of 10 µM MPEP. Filtration and measuring were as described above.

IV.5.8. Data Analysis.

Results are expressed as means ± SEM for at least three experiments, each performed in duplicate. Statistical analysis and curve fits of dose-response curves were performed using GraphPad Prism 7. Ki values were calculated by using the Cheng-Prusoff equation.[68]

IV.5.9. MAPK phosphorylation

HEK293S cells stably expressing HA D4.2R were seeded in 6-well plates with 400,000 cells per well. When the cells were 70% confluent, cells were starved overnight with serum free medium. The ligands (1 nM-10 µM) were added sequentially to the cells at the concentrations indicated in the legend for 5 min. To stop the reaction, medium was aspirated, the cells were placed on ice and washed with ice-cold PBS. RIPA buffer [150 mM NaCl; 50 mM Tris/HCl pH 7.5; 1 % NP-40; 0.1 % SDS; and 0.5 % deoxycholic acid sodium salt (Acros Organics: 218591000); protease inhibitors: aprotinin (2.5 µg/ml, Sigma-Aldrich: A6279), pefablock (1 mM, Sigma-Aldrich: 76307), leupeptin (10 µg/ml, Acros Organics: 328350050), and phosphatase inhibitor β-glycerol phosphate disodium salt pentahydrate (10 mM, Fluka BioChemika: 50020)] was used to prepare the cell lysate for western blotting according to the protocol described before.[69] After western blotting, the membrane was incubated with blocking buffer (LI-COR Biosciences) for 1h at RT. Then, primary antibody rabbit polyclonal phospho-p44/42 MAPK (1/2000) (Cell Signaling, cat. no. 9101L) or mouse monoclonal p44/42 MAPK (1/2000) (clone L34F12; Cell Signaling, cat. no. 4696S) was added to develop the blot overnight at 4 °C. Next, the blot was washed with washing buffer (PBS + 0.05% Tween 20 from Sigma-Aldrich) for three times and then secondary antibodies goat anti-rabbit IRDye680 LT (1/10000) (cat. no. 926–68021, LI-COR Biosciences) or goat anti-mouse IRDye800 (1/10000) (cat. no.926–32210, LI-COR Biosciences) were added for 1h at RT in the dark. The blot was washed with washing buffer for three times and the fluorescent signal was detected with the Odyssey Infrared Imaging system. In the analysis, the phospho-p44/42 MAPK signal is normalized against the total p44/42 MAPK signal after quantification by Image J.

IV.5.10. GloSensor cAMP protocol

HEK293T D2s-mGluR5 co-expressing cells and HEK293T D2s cells were seeded in 6-well plates at 500 000 cells/well. The day after, cells were transfected with the pGloSensor-22F cAMP plasmid, using the FuGene transfection reagent (as described previously).[44]

Cells were first washed with CO₂-independent medium and afterwards incubated with equilibration medium containing 2% v/v GloSensor cAMP reagent stock solution in 10% FBS CO₂-independent medium. After an incubation of 30 min at 37 °C, the luminescence signal was measured until a steady-state basal signal was obtained. Serial concentrations of monovalent agonist DPAT-alkyne (**3.07**) or bivalent ligand (**4.20a**) (0.1 nM-10 µM) were added. After 15 min, 10 µM Forskolin (FSK) was added. The agonist profile of the compounds was evaluated by assessing their ability to counteract the Forskolin-induced increase of cAMP accumulation. Therefore, the maximal luminescent responses were used for generating dose-response curves and EC₅₀-values.

IV.5.11. Computational modeling

IV.5.11.1 Receptor structure preparation

Crystallographic missing residues and/or atoms in the human D₂R crystal structure[47] (PDB id: 6CM4) were added using CHIMERA v1.11.2 software[70] by selecting the most probable rotamer at relevant positions with fewest possible steric clashes. Mutated residues: I122A, L375A, L379A were converted back to wild-type using the same procedure. The four-residue missing segment of intracellular loop 2 (ICL2) was *ab initio* modeled with MODELLER v9.18.[71] Co-crystallized risperidone and endolysin fusion protein were removed from the D₂R structure. Energy minimization was then performed on added residues/loops and any clashing atoms in the AMBER14SB force-field.[72]

From a previously published MD simulation of mGlu5 with bound NAM,[50] a conformation of mGlu5 was extracted which has a larger extracellular gap between TM5 and TM6 than the original crystal structure[46] (PDB id: 4009). The simulated NAM was removed from this structure.

IV.5.11.2 Protein-protein docking

For construction of an mGluR5-D2R heterodimer model, where D₂R and mGluR5 interact via a symmetrical TM5-TM6 interface, both receptors were systematically superimposed onto relevant monomers of the mu-opioid receptor homodimer crystal structure[59] (PDB id: 4DKL). The mGluR5-D₂R heterodimer model was then submitted to the ROSIE webserver[60] for protein-protein docking using default parameters. The best docked heterodimer structure was identified by two factors: best interface score (“I_sc”) and best membrane-compatible orientation.

IV.5.11.3 Bivalent ligand docking

Coordinates for MTEP and 5-OH-DPAT were downloaded from PubChem.[73] Autodock v4.2[74] was used to dock MTEP into mGluR5 and 5-OH-DPAT into D₂R in the heterodimer model. Grid points were extended to cover total allosteric and orthosteric pocket volumes, respectively. The selected docked conformation of each ligand in its receptor represents the top hit identified by best predicted affinity in the largest docking cluster. The linker between MTEP and 5-OH-DPAT components, corresponding to compound **4.20a**, was modeled with CHIMERA by manually extending the chain from both sides and connecting at the heterodimer interface between TM5 and TM6 of both receptors. The **4.20a** linker was modeled to follow the shortest path possible between receptors whilst avoiding steric clashes. The heterodimer-ligand complex was energy minimized without restraints with CHIMERA in the AMBER-14SB force-field[72] to relax the **4.20a** linker and optimize protein-ligand interactions.

IV.6. Supporting information

Synthesis towards bivalent ligands for the dopamine D₂ and metabotropic glutamate 5 receptors

Table of contents

Synthesis of linker and bivalent ligands	S1
Ligand binding assays	S2
MAPK phosphorylation for D ₄ R, D ₂ R and mGluR5	S3
Experimental Section	S4
Chromatographic analyses for bivalent ligands	S5
NMR spectra	S6

S1

Synthesis of tertiary amine linker

Scheme 1. Reagents and conditions: i) **4.13c**, Na(OAc)₃BH, CH₂Cl₂; ii) TFA, CH₂Cl₂, 4 M NaOH

Synthesis of bivalent ligands

Scheme 2. Reagents and conditions: i) (3-dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride, 1-hydroxybenzotriazole, triethylamine, CH₂Cl₂; ii) sodium ascorbate, CuSO₄, triethylamine, tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine, dimethylformamide.

S2

Table 1 Binding affinities (K_i) for D₄R

Compound	X	R	Linker	K_i (nM) for D ₄ R
3.07	-	DPAT	-	15 ± 6.1
3.03	-	DAP	-	1.6 ± 0.2
4.16	N	DPAT	-OCH ₂ CONH (CH ₂) ₆ -	62 ± 8.3
4.20a	N	DPAT	-OCH ₂ CONH(CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	21 ± 2.4
4.20b	N	DPAT	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	64 ± 2.9
4.21a	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	4.3 ± 0.2
4.21b	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	9.4 ± 1.6
4.21c	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	5.6 ± 1.8
4.21d	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	7.3 ± 0.8
4.18a	CH	DAP	-OCH ₂ CONH-PEG ₄ -	189 ± 12
4.18b	CH	DAP	-OCH ₂ CONH-PEG ₆ -	23 ± 3.7

Binding affinities (K_i) were obtained by competitive displacement of radiolabeled [³H]spiperone binding to HEK293T D₄R cell membranes. All values are expressed as the mean ± SEM of three independent assays performed in duplicate.

Saturation assay for mGluR5

Entry	Bmax fmol/mg	Kd nM
mGluR5	1488 ± 153	2.2 ± 0.7
mGluR5-D ₂ R	522 ± 19	2.0 ± 0.2

All values are expressed as the mean ± SEM of two independent assays performed in duplicate.

S3

MAPK phosphorylation for D₄R

(A)

(B)

(C)

(D)

Figure 1. Efficacy of bivalent ligands to phosphorylate MAPK in HEK293 D₄R cells. Cells were treated with serum-free media (SFM) for 12 h. Next, D₂-likeR agonists and SFM were added for 5 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Cells treatment with SFM served as control. The panels A and C show a representative result from three independent experiments; the panels B and D are given as mean \pm SEM. DA=dopamine.

MAPK phosphorylation for D₂R-mGluR5

Figure 2. Efficacy of bivalent ligands to phosphorylate MAPK in HEK293 D₂R-mGluR5 cells. Cells were treated with serum-free media (SFM) for 12 h. Next, D₂-likeR agonists and SFM were added for 5 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Cells treatment with SFM served as control. The left panel shows a representative result from three independent experiments; the right panel is given as mean \pm SEM. DA=dopamine. * $p < 0.05$ and ** $p < 0.01$. ns, not significant.

MAPK phosphorylation for mGluR5

Figure 3. Time-dependent response on activity of MAPK-P by L-Glu and CHPG in HEK293 mGluR5 cells. Cells were treated with serum-free media (SFM) for 12 h. Next, mGluR5 agonists, SFM or vehicle control were added for 5 min or 10 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Cells treatment with SFM served as control. The left panel shows a representative result from three independent experiments; the right panel is given as mean \pm SEM. L-Glu = L-Glutamic acid. CHPG = (RS)-2-Chloro-5-hydroxyphenylglycine. * $p < 0.05$, **** $p < 0.0001$.

Figure 4. Efficacy of one bivalent ligand **4.20a** and MTEP to inhibit phosphorylation of MAPK activated by L-Glu in HEK293 mGluR5 cells. Cells were treated with serum-free media (SFM) for 12 h and then pretreated with or without MTEP and **4.20a** (10 μ M) for 30 min before treatment with L-Glu (10 μ M, 10 min). Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Results are expressed as the fold of control. Cells treatment with SFM served as control. The left panel shows a representative result from three independent experiments; the right panel is given as mean \pm SEM. L-Glu = L-Glutamic acid.

Figure 5. Efficacy of bivalent ligands to inhibit phosphorylation of MAPK activated by L-Glu in HEK293 mGluR5 cells. Cells were treated with serum-free media (SFM) for 12 h and then pretreated with or without MTEP and bivalent ligands (10 μ M) for 30 min before treatment with L-Glu (10 μ M, 10 min). Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Results are expressed as the fold of control. Cells treatment with SFM served as control. The top panel shows a representative result from three independent experiments; the bottom panel is given as mean \pm SEM. L-Glu = L-Glutamic acid.

Figure 6. Time-dependent response on activity of MAPK-P by 10 μ M L-Glu in HEK293 mGluR5-D₂R cells. Cells were treated with serum-free media (SFM) for 12 h. Next, SFM and mGluR5 agonist were added for 3 min, 5 min 7 min, 10 min or 15 min. Cells were washed and lysed as explained in the Experimental section. Phosphorylated MAPK was detected by immunoblotting using rabbit anti-phospho-p44/42 MAPK antibody and mouse anti-p44/42 MAPK antibody was used for demonstrating equal protein loading. Cells treatment with SFM served as control. The left panel shows a representative result from three independent experiments; the right panel is given as mean \pm SEM. L-Glu = L-Glutamic acid. * p < 0.05, *** p < 0.001 and **** p < 0.0001. ns, not significant.

Table 2. Overview of MAPK-P for D₄R and mGluR5.

Entry	X	R	Linker	MAPK for D ₄ R	MAPK for mGluR5
3.03	-	-	-	+	-
3.07	-	-	-	+	-
MTEP	-	-	-	-	+
4.20a	N	DPAT	-OCH ₂ CONH(CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	+	+
4.20b	N	DPAT	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	+	+
4.20c	N	DPAT	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₂ -	+	+
4.20d	CH	DPAT	-OCH ₂ CONH(CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	+	+
4.20e	CH	DPAT	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	+	+

4.21a	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	+	+
4.21b	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	+	+
4.21e	N	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₂ -	+	+
4.21c	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₈ -	+	+
4.21d	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₀ -	+	+
4.21f	CH	DAP	-OCH ₂ CONH (CH ₂) ₅ NCH ₃ (CH ₂) ₁₂ -	+	+
4.16	N	DPAT	-OCH ₂ CONH (CH ₂) ₆ -	+	+
4.16b	N	DAP	-OCH ₂ CONH (CH ₂) ₆ -	+	+
4.16a	CH	DPAT	-OCH ₂ CONH (CH ₂) ₆ -	+	+
4.16c	CH	DAP	-OCH ₂ CONH (CH ₂) ₆ -	+	+
4.18d	N	DAP	-OCH ₂ CONH-PEG ₆ -	+	+
4.22a	N	DPAT	-OCH ₂ CONH-PEG ₆ -	+	+
4.18c	N	DAP	-OCH ₂ CONH-PEG ₄ -	+	+
4.22b	N	DPAT	-OCH ₂ CONH-PEG ₄ -	+	+
4.18b	CH	DAP	-OCH ₂ CONH-PEG ₆ -	+	+
4.22c	CH	DPAT	-OCH ₂ CONH-PEG ₆ -	+	+
4.18a	CH	DAP	-OCH ₂ CONH-PEG ₄ -	+	+
4.22d	CH	DPAT	-OCH ₂ CONH-PEG ₄ -	+	+

“+” means MAPK works for D₄R or mGluR5.

S4

Experimental Section**General procedure 1:** Carbodiimide-mediated amide formation.

To a solution of (3-Dimethylaminopropyl)-N-ethylcarbodiimide hydrochloride (1.5 eq.) and 1-hydroxybenzotriazole (1.4 eq.) in CH₂Cl₂ was added a solution of the PEG spacer (1.2 eq.) in CH₂Cl₂ (0.2 M) and cooled to 0°C under an argon atmosphere. After 15 min at 0°C, amines (1.0 eq.) were added and triethylamine (2 eq.) was added dropwise; the reaction was slowly warmed to room temperature and stirred overnight. The reaction was diluted with CH₂Cl₂, washed successively with water, HCl (5% aq.), NaHCO₃ (sat. aq.), NaCl (sat. aq.), dried over Na₂SO₄, filtered and solvent was evaporated under reduced pressure. The crude product was purified by silica gel chromatography (NH₄OH/MeOH/CH₂Cl₂, 1:5:94 v/v/v) to yield the amides.

General procedure 2: Copper mediated azide-alkyne cycloaddition.

To a solution of the intermediate azide (1.0 eq.) in dimethylformamide (0.1 M) was added the alkyne (1.5 eq.), sodium ascorbate (1.0 eq., 0.5 M), CuSO₄ (0.2 eq., 0.05 M), triethylamine (3.0 eq.) and a catalytic amount of tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine. The reaction mixture was stirred overnight at room temperature in the dark under an argon atmosphere. The solvent was evaporated under reduced pressure and the residue was redissolved in water and extracted with CH₂Cl₂. Then combined organic fractions were pooled, washed with brine and dried over Na₂SO₄. The crude compound was purified by silica gel chromatography (NH₄OH/MeOH/CH₂Cl₂, 1:5:94 v/v/v) to give the final compound as a white solid.

12-azidododecanal (4.13c)

Compound **4.13c** was prepared using the procedure described as **4.13a**. Colorless oil (3.4 g, 89%). ¹H NMR (300 MHz, CDCl₃) δ 9.71 (s, 1H), 3.21 (t, *J* = 6.9 Hz, 2H), 2.37 (td, *J* = 7.4, 1.9 Hz, 2H), 1.68 – 1.48 (m, 4H), 1.37 – 1.16 (m, 14H). ¹³C NMR (75 MHz, CDCl₃) δ 202.9, 51.4, 43.8, 29.4, 29.3, 29.3, 29.1, 29.1, 29.1, 28.8, 26.6, 22.0.

***tert*-butyl (5-((12-azidododecyl)(methyl)amino)pentyl)carbamate (4.14c)**

Compound **4.14c** was obtained according to the procedure described for compound **4.14a**. Colorless oil (3.31 g, 78%). ¹H NMR (300 MHz, CDCl₃) δ 4.61 (s, 1H), 3.22 (t, *J* = 6.9 Hz, 2H), 3.08 (q, *J* = 6.6 Hz, 2H), 2.53 – 2.42 (m, 4H), 2.33 (s, 3H), 1.63 – 1.43 (m, 6H), 1.41 (s, 9H), 1.37 – 1.17 (m, 20H). ¹³C NMR (75 MHz, CDCl₃) δ 155.9, 79.0, 56.8 (d, *J* = 17.9 Hz), 51.4, 41.2, 40.3, 29.7, 29.4, 29.4, 29.4,

29.3, 29.1, 28.7, 28.4, 27.3, 26.6, 25.7 (d, $J = 26.6$ Hz), 24.5. HRMS (ESI) m/z : calculated for $C_{23}H_{48}N_5O_2$ $[M+H]^+$ 426.3808; found 426.3807.

***N*¹-(12-azidododecyl)-*N*¹-methylpentane-1,5-diamine (4.04c)**

Compound **4.04c** was obtained according to the procedure described for compound **4.04a**. Colorless oil (2.4 g, 95%). 1H NMR (300 MHz, DMSO- d_6) δ 3.27 (t, $J = 6.8$ Hz, 2H), 2.81 – 2.74 (m, 2H), 2.48 (dq, $J = 3.1, 1.5$ Hz, 4H), 2.41 (s, 3H), 1.70 – 1.39 (m, 6H), 1.36 – 1.17 (m, 20H). ^{13}C NMR (75 MHz, DMSO- d_6) δ 55.4, 51.0, 48.6, 40.7, 39.0, 38.9, 32.8, 31.0, 29.4, 28.9, 28.6, 26.8, 26.5, 26.3, 26.2, 25.7, 23.7, 23.2. HRMS (ESI) m/z : calculated for $C_{18}H_{40}N_5$ $[M+H]^+$ 326.3284; found 326.3288.

***N*-(6-azidohexyl)-2-((2-methylthiazol-4-yl)ethynyl)phenoxy)acetamide (4.15a)**

Compound **4.15a** was subjected to general procedure 1. Offwhite solid, 78%. 1H NMR (300 MHz, $CDCl_3$) δ 7.37 (s, 1H), 7.30 – 7.24 (m, 1H), 7.20 (dt, $J = 7.7, 1.3$ Hz, 1H), 7.09 (ddd, $J = 2.7, 1.4, 0.4$ Hz, 1H), 6.90 (ddd, $J = 8.1, 2.7, 1.2$ Hz, 1H), 6.54 (br s, 1H), 4.47 (s, 2H), 3.33 (td, $J = 7.1, 6.0$ Hz, 2H), 3.23 (t, $J = 6.8$ Hz, 2H), 2.72 (s, 3H), 1.81 (br s., 1H), 1.63 – 1.48 (m, 4H), 1.44 – 1.27 (m, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ 167.7, 165.8, 156.9, 136.5, 129.8, 125.6, 124.1, 122.6, 117.6, 115.4, 88.0, 83.9, 67.4, 51.3, 38.8, 29.4, 28.7, 26.3, 19.1. HRMS (ESI) m/z : calculated for $C_{20}H_{24}N_5O_2S$ $[M+H]^+$ 398.1651; found 398.1637.

***N*-(5-((12-azidododecyl)(methyl)amino)pentyl)-2-((5-((2-methylthiazol-4-yl)ethynyl)pyridin-3-yl)oxy)acetamide (4.19e)**

Compound **4.19e** was subjected to general procedure 1. Offwhite solid, 69%. 1H NMR (300 MHz, $CDCl_3$) δ 8.44 (d, $J = 1.6$ Hz, 1H), 8.29 (d, $J = 2.9$ Hz, 1H), 7.43 (s, 1H), 7.33 (dd, $J = 2.9, 1.6$ Hz, 1H), 6.55 (t, $J = 6.2$ Hz, 1H), 4.50 (s, 2H), 3.34 (q, $J = 7.0$ Hz, 2H), 3.22 (t, $J = 7.0$ Hz, 2H), 2.72 (s, 3H), 2.30 (dt, $J = 8.2, 5.4$ Hz, 4H), 2.19 (s, 3H), 1.64 – 1.54 (m, 4H), 1.52 – 1.39 (m, 2H), 1.39 – 1.18 (m, 20H). ^{13}C NMR (75 MHz, $CDCl_3$) δ 166.7, 152.7, 145.9, 138.0, 123.5, 123.1, 120.2, 87.1, 84.7, 67.5, 57.8, 57.5, 51.4, 42.1, 39.1, 29.8 – 29.3 (wide peak), 29.1, 28.8, 27.5, 27.1, 26.8, 26.7, 24.7, 21.0, 19.3, 14.1. HRMS (ESI) m/z : calculated for $C_{31}H_{48}N_7O_2S$ $[M+H]^+$ 582.3590; found 582.3596.

***N*-(5-((12-azidododecyl)(methyl)amino)pentyl)-2-(3-((2-methylthiazol-4-yl)ethynyl)phenoxy)acetamide (4.19f)**

Compound **4.19f** was subjected to general procedure 1. Offwhite solid, 75%. 1H NMR (300 MHz, $CDCl_3$) δ 7.37 (s, 1H), 7.31 – 7.25 (m, 1H), 7.21 (dt, $J = 7.6, 1.3$ Hz, 1H), 7.11 – 7.08 (m, 1H), 6.91 (ddd, $J = 8.1, 2.6, 1.2$ Hz, 1H), 6.55 (t, $J = 5.9$ Hz, 1H), 4.47 (s, 2H), 3.39 – 3.29 (m, 2H), 3.23 (t, $J = 7.0$ Hz, 2H), 2.73 (s, 3H), 2.30 (ddd, $J = 7.8, 6.5, 3.6$ Hz, 4H), 2.19 (s, 3H), 1.64 – 1.40 (m, 6H), 1.38 – 1.20 (m, 20H). ^{13}C NMR (75 MHz, $CDCl_3$) δ 167.6, 165.7, 156.9, 136.6, 129.7, 125.6, 124.0, 122.5, 117.6, 115.5, 115.4,

88.1, 83.8, 67.4, 57.8, 57.5, 51.4, 42.2, 39.1, 29.6, 29.5, 29.4, 29.4, 29.1, 28.8, 27.5, 27.1, 26.8, 26.7, 24.7, 19.2, 14.2. HRMS (ESI) m/z : calculated for $C_{32}H_{49}N_6O_2S$ $[M+H]^+$ 581.3638; found 581.3651.

CHAPTER V

Synthesis and biological evaluation of fluorescent ligands targeting the metabotropic glutamate 5 receptor

Víctor Fernandez Dueñas performed all the biological assays under supervision of Prof. Francisco Ciruela (Universitat de Barcelona). Dr. Martijn Risseuw synthesized the BODIPY dye reagents.

V. SYNTHESIS AND BIOLOGICAL EVALUATION OF FLUORESCENT LIGANDS TARGETING THE METABOTROPIC GLUTAMATE 5 RECEPTOR

V.1. Abstract

In this study, we described the design and synthesis of a series of fluorescent mGluR5 ligands based on BODIPY fluorophores. The preliminary evaluation via NanoBRET suggests that all the fluorescent ligands are able to bind to the mGluR5. In addition, the affinity of compound **5.03** to mGluR5 seems modestly higher than that of **5.10** in the saturation assay. Hence, **5.03** could be a promising tool for further investigating D₂R-mGluR5 dimerization at the surface of living cells by NanoBRET.

V.2. Introduction

The metabotropic glutamate receptors (mGluRs) constitute a family of G-protein coupled receptors (GPCR) in the mammalian central nervous system (CNS) and are characterized by the presence of large, extracellular, N-terminal orthosteric binding domains, which are activated by L-glutamate [1][2][3]. Group I mGluRs (mGluR1 and mGluR5) are principally localized postsynaptically and are extensively distributed in many brain regions, including the hippocampus, thalamic nuclei, and spinal cord. Stimulation of mGluR5 leads to phosphoinositide (PI) hydrolysis and formation of two intracellular second messengers: inositol triphosphate (IP₃), which induces intracellular Ca²⁺ release, and diacylglycerol (DAG), which stimulates protein kinase C activity (PKC), via Gq protein coupling to phospholipase C [3][4][5].

Fluorescently labeled ligands have proven their utility as pharmacological tools to study receptor localization, trafficking, and signaling processes via fluorescence imaging [6]. They are also employed in fluorescent binding assays to study ligand/receptor interactions [6]. In such competition assays, fluorescent ligands offer advantages over radioligands, which suffer from health risks and legal and disposal costs.

V.3. Design of fluorescent mGluR5 ligands

Boron dipyrromethene (BODIPY) is a fluorescent dye with diverse properties, such as photochemical stability, high molar absorptivity, high fluorescence quantum yield, and the fact that its fluorescence property can be altered by varying the substitution pattern on the core and the flanking pyrroles. Alkyne functionalized BODIPY dyes can be used to fluorescently label an azido functionalized ligand in a chemo selective manner employing the copper-catalyzed azide–alkyne cycloaddition (CuAAC) reaction [7]. Here we exploited alkyne functionalized BODIPY (496/503) and BODIPY (573/607) to construct a small set of fluorescent mGluR5 ligands (Figure 1). Towards this end, we employed the earlier

synthesized MTEP derivatives and linkers as used for the bivalent D₂R-mGluR5 ligands. These fluorescent ligands were tested by NanoBRET. NanoBRET is a relatively new bioluminescence resonance energy transfer (BRET) variant for the analysis of protein-protein interactions, which was developed by Promega by combining an extremely bright luciferase (Nanoluc) with BRET to increase detection sensitivity and dynamic range over current BRET technologies [8].

Figure 1. Designed fluorescent mGluR5 ligands based on BODIPY

V.4. Results and discussion

V.4.1. Chemistry

V.4.1.1 Synthesis of fluorescent mGluR5 ligands

The fluorescent ligands were generated by first condensing the mGluR5 carboxylate derivatives with different spacers in the presence of the coupling agent EDC and triethylamine to yield the six intermediate azides, which were described in Chapter IV. The synthesis of the fluorescent ligands was accomplished by reacting each of these azides with both alkyne modified BODIPY green and BODIPY red through CuAAC (Scheme 1). This afforded a concise series of twelve mGluR5 fluorescent ligands.

5.01: X=N, n=4
5.02: X=CH, n=2

5.05: X=CH, n=5
5.06: X=N, n=5

Scheme 1. Reagents and conditions: a) sodium ascorbate, CuSO₄, triethylamine, tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine, dimethylformamide.

V.4.2. Preliminary evaluation of the synthesized fluorescent mGluR5 ligands

V.4.2.1 Characterization of fluorescent properties

We first determined the excitation and emission spectra of the fluorescent mGluR5 ligands. All BODIPY green labeled ligands exhibited comparable spectral separation (10 nm) between excitation and emission wavelength (Figure 2). Interestingly, spectral separation exceeding more than 30 nm was achieved for the three measured BODIPY red labeled ligands, with **5.03** even displaying spectral separation of 40 nm.

Figure 2. Excitation and emission wavelength for the mGluR5 fluorescent ligands.

Next, we tested the emission intensity for all the BODIPY labeled ligands. Compound **5.01** (Figure 3) showed higher emission intensity than the other BODIPY green labeled ligands. Within the red labeled ligands compounds **5.03** and **5.10** displayed the highest emission intensity. Of note, compounds **5.01** and **5.03** share the same length and composition of spacer (PEG₆).

Figure 3. Relative emission at 560 nm or 649 nm of a 10 μ M solution of the different BODIPY-conjugates in 0.05% DMSO upon excitation at 480 nm or 550 nm, respectively. This value is somehow related to the quantum yield of each fluorophore.

V.4.2.2 Fluorescent mGluR5 ligands in the NanoBRET assay

Using a mGluR5 that is tagged at its N-terminus with a small, bright Nanoluciferase as a luminescent donor we evaluated the intensity of the NanoBRET signal upon incubation with the different synthesized fluorescent mGluR5 ligands as acceptors. This signal originates from the bioluminescence resonance energy transfer between the NanoLuc and BODIPY labeled ligand in the presence of coelenterazine.[8]

First a binding assay was performed to assess the ability of the fluorescent mGluR5 ligands (10 μ M) to generate NanoBRET signals. BODIPY green labeled compounds had a comparable signal at 554 nm except for **5.02** and **5.11**, which gave a considerably lower NanoBRET signal. Amongst the BODIPY red labeled ligands, compound **5.03** exhibited the highest efficacy to generate NanoBRET signal at 610 nm.

Figure 4. Represents the binding of 10 μ M of each ligand to mGluR5^{NL} (a single concentration binding assay). Binding conditions: HEK-293 transiently transfected with mGluR5^{NL} were incubated with 10 μ M fluorescent ligands in the absence or presence of 100 μ M MTEP during 1h at 22°C.

Subsequently, a saturation assay was performed to assess the binding affinity of fluorescent ligands to mGluR5. Preliminary results indicate that the binding affinity of compound **5.03** (0.84 ± 0.74 μ M) is

modestly higher than that of **5.10** ($1.4 \pm 1.2 \mu\text{M}$). However, the B_{max} values for these two compounds are reversed. In addition, we also tested the expression of the receptor $\text{mGluR5}^{\text{NL}}$, which was constructed in HEK 293T cells.

Figure 5. Saturation binding assay for the fluorescent mGluR5 ligands via NanoBRET.

V.5. Conclusion

In summary, we have designed and synthesized twelve novel fluorescent mGluR5 ligands based on BODIPY fluorophores. The preliminary biological assessment via NanoBRET indicates that all the fluorescent ligands are capable of binding to the mGluR5. Furthermore, although the saturation assay needs to be optimized, the affinity of compound **5.03** to mGluR5 seems modestly higher than that of **5.10**. Therefore, **5.03** could be a promising tool for investigating D_2R -mGluR5 dimerization at the surface of living cells by NanoBRET (Figure 6).

Figure 6. A NanoBRET approach will be used to assess mGluR5-D₂R oligomerization.

V.6. Experimental

V.6.1 Chemistry

All reactions described were performed under an N₂ atmosphere and at ambient temperature unless stated otherwise. All reagents and solvents were purchased from Sigma-Aldrich (Diegem, Belgium), Fisher Scientific (Merelbeke, Belgium), TCI Europe (Zwijndrecht, Belgium) or Apollo Scientific (Bredbury, Stockport, United Kingdom) and used as received. NMR solvents were acquired from Eurisotop (Saint-Aubin, France). Reactions were monitored by TLC analysis using TLC aluminium sheets (Macherey-Nagel, Alugram Sil G/UV254) with detection by spraying with a solution of (NH₄)₆Mo₇O₂₄·4H₂O (25 gL⁻¹) and (NH₄)₄Ce(SO₄)₄·2H₂O (10 gL⁻¹) in H₂SO₄ (10 % aq.) followed by charring or an aqueous solution of KMnO₇ (20 gL⁻¹) and K₂CO₃ (10 gL⁻¹) or an ethanolic solution of ninhydrin (2 gL⁻¹) and acetic acid (1% v/v) followed by charring. Solution pH values were estimated using universal indicator paper (Merck). Silica gel column chromatography was performed using a Grace Reveleris X2 system and the corresponding silica gel cartridges. ESI-HRMS spectra were measured with a Waters LCT Premier XE Mass spectrometer calibrated using leucine enkephalin as an external standard. ¹H- and ¹³C-APT-NMR spectra were recorded with a Varian Mercury-300BB (300/75 MHz) spectrometer. Chemical shifts are given in ppm (δ) relative to tetramethylsilane as an internal standard (¹H NMR) or the NMR solvent (¹³C NMR). Coupling constants are given in Hertz (Hz). Weak signals in ¹³C NMR are indicated as (w). LC-MS analyses were carried out on a Waters AutoPurification System equipped with PDA and ESI-MS detection and using a Waters CORTECS C18 Column (4.6×100 mm, 2.7μm) and a water/acetonitrile/formic acid linear gradient system at a flow rate of 1.44 mLmin⁻¹.

General procedure 1: Copper mediated azide-alkyne cycloaddition.

To a solution of the intermediate azide (1.0 eq.) in dimethylformamide (0.1 M) was added the alkyne (1.5 eq.), sodium ascorbate (1.0 eq., 0.5 M), CuSO₄ (0.2 eq., 0.05 M), triethylamine (3.0 eq.) and a catalytic amount of tris[(1-benzyl-1,2,3-triazol-4-yl)methyl]amine. The reaction mixture was stirred overnight at room temperature in the dark under an argon atmosphere. The solvent was evaporated under reduced pressure and the residue was redissolved in water and extracted with CH₂Cl₂. Then combined organic fractions were pooled, washed with brine and dried over Na₂SO₄. The crude compound was purified by silica gel chromatography (NH₄OH/MeOH/CH₂Cl₂, 1:5:94 v/v/v) to give the final compound as a white solid.

N-(17-(4-(4-(5,5-difluoro-1,3,7,9-tetramethyl-5H-4λ⁴,5λ⁴-dipyrrolo[1,2-c:2',1'-f][1,3,2]diazaborinin-10-yl)butyl)-1H-1,2,3-triazol-1-yl)-3,6,9,12,15-pentaoxaheptadecyl)-2-((5-((2-methylthiazol-4-yl)ethynyl)pyridin-3-yl)oxy)acetamide (5.01)

Compound **5.01** was subjected to general procedure 1. Brown semi-solid, 42%.

LC-HRMS: t_R =6.77 min (10–100% MeCN, 15 min run), purity 92.98 %.

V.6.2 Spectra

The fluorescent ligands were re-suspended in DMSO, to a final concentration of 20 mM. Next, a working solution of 10 μ M was prepared and dispensed (100 μ L) into a 96-wells plate. The protocols for excitation and emission spectra were selected in the CLARIOstar plate reader (BMG Labtech, Durham, NC, USA).

V.6.3 Relative emission

The relative emission of the different ligands was assessed by exciting the fluorophores at the wavelength corresponding to the excitation peak. Accordingly, a working solution of 10 μ M was prepared and dispensed (100 μ L) into a 96-wells plate. Then, BODIPY green compounds were excited at 480-10 nm and emission read at 560-20 nm; while BODIPY red compounds were excited at 550-10 nm and emission read at 650-20 nm, using the CLARIOstar plate reader (BMG Labtech).

V.6.4 Single binding NanoBRET assay

The NanoBRET assay was performed on transfected (mGlu₅R^{NL}) HEK 293T cells. In brief, cells were re-suspended in HBSS, and seeded into poli-ornitine coated white 96-well plates. After 24 hours, cells were challenged with the fluorescent ligands and the plate returned to 37°C for 1 h. Finally, *h*-Coelenterazine (Life Technologies Corp) was added at a final concentration of 5 μ M, and readings were performed after 5 min using a CLARIOstar plate reader (BMG Labtech). The donor and acceptor emission was measured at 490-10 nm and 560-80 for the BODIPY green compounds and 650-80 nm for the BODIPY red compounds, respectively. The raw NanoBRET ratio was calculated by dividing the 560 nm or 650 nm emission by the 490 nm emission. Results were expressed as a percentage of the maximum signal obtained (mBU; miniBRET Units).

V.6.5 Saturation binding NanoBRET assay

The NanoBRET assay was performed on transfected (mGlu₅R^{NL}) HEK 293T cells. In brief, cells were re-suspended in HBSS, and seeded into poli-ornitine coated white 96-well plates. After 24 hours, cells were challenged with/without the non-labelled mGlu₅R selective allosteric antagonist (MTEP) and incubated for 1 h at 37°C. Subsequently, the increasing concentrations of the fluorescent ligands (**5.03**

and **5.10**) were added and the plate returned to 37°C for 1 h. Finally, *h*-Coelenterazine (Life Technologies Corp) was added at a final concentration of 5 µM, and readings were performed after 5 min using a CLARIOstar plate reader (BMG Labtech). The donor and acceptor emission was measured at 490-10 nm and 650-80 nm, respectively. The raw NanoBRET ratio was calculated by dividing the 650 nm emission by the 490 nm emission. Results were expressed as a percentage of the maximum signal obtained (mBU; miliBRET Units).

V.7. Supporting Information

V.7. 1. Generation of a mGlu₅ receptor NanoLuc

Figure 1 clearly shows a protein concentration-dependent expression of mGluR5^{NL} in HEK 293T cells.

Figure 1. Expression of the mGluR5^{NL} construct in HEK293T cells.

Gel electrophoresis and immunoblotting

Total membrane extracts from transiently transfected HEK-293T cell were prepared as previously described.[1],[2] Protein concentration was determined using the BCA protein assay kit (Thermo Fisher Scientific, Inc., Rockford, IL, USA).

Extracts were analyzed by sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS/PAGE) using 7% polyacrylamide gels. Separated proteins were transferred to polyvinylidene difluoride (PVDF) membranes using a semi-dry transfer system (Bio-Rad, Hercules, CA, USA), immunoblotted with the indicated antibody and then with the horseradish peroxidase (HRP)-conjugated corresponding secondary antibody. The immunoreactive bands were developed using a chemiluminescent detection kit (Thermo Fisher Scientific, Waltham, MA, USA) and detected with an Amersham Imager 600 (GE Healthcare Europe GmbH, Barcelona, Spain).[3]

V.7. 2. Chromatographic analyses

LC-MS analyses were carried out on a Waters Alliance 2695 XE separation Module by using a Phenomenex Kinetex EVO C18, 5 μ m 100x2.1mm and a gradient system of HCOOH in H₂O (0.1 %, v/v)/HCOOH in MeCN (0.1%, v/v) at a flow rate of 0.6 mLmin⁻¹, 100:0 to 0:100 (0 to 100 % MeCN) in 15 minutes. High-resolution spectra were recorded on a Waters LCT Premier XE Mass spectrometer and a 2996 Photodiode Array Detector, range 220 nm-400 nm.

CHAPTER VI

General conclusion

VI. GENERAL CONCLUSION

Firstly, we designed and synthesized a series of novel heterobivalent ligands based on the chemical structure of two distinct D₂-likeR ligands and a μ OR agonist, as well as a μ OR antagonist. The ketone group from HM and NTX was converted to the corresponding 6'-*R*-amino derivatives **3.02a** and **3.02b** to allow coupling with the linker via an amide bond. As D₂-likeR ligands we used the antagonist 1,4-DAP and agonist 5-OH-DPAT that were equipped with an appropriate alkyne, which allowed facile connection to the azido group on the PEG linker via a copper-catalyzed azide-alkyne cycloaddition (CuAAC) reaction. The dimeric D₂-likeR- μ OR ligands were constructed around PEG spacers of variable length that were equipped with a carboxylic acid on one and an azide on the other end (Figure 1). The use of PEG linkers precludes cumulative incremental increases in hydrophobicity that would occur upon homologation if an alkyl chain were employed. The choice of the position and nature of the attachment points for linking the two pharmacophore units to the spacer relied on two criteria: the feasibility of the chemical modification and the compatibility of the modification with the biological activity of the pharmacophore.

Figure 1. Schematic overview of strategies, monovalent ligands and spacers with appropriate ligation handles.

Ligation of μ OR ligands did not perturb the affinity for μ OR. μ OR bivalent ligands derived from the HM agonist are still capable of activating the μ OR signaling pathway as demonstrated by β -arrestin2 recruitment. Furthermore, bivalent ligand **3.12d** containing the shortest linker (18-atom) showed excellent potency and high efficacy both in β -arrestin2 recruitment for μ OR and MAPK-P for D₄R. On

the other hand, ligation of D₂-likeR ligands negatively influenced the affinity for D₂R and D₄R in a competition experiment with [³H]spiperone. However, a biphasic competition-binding curve was observed for **3.12d** to D₄R-μOR, which indicates a bivalent binding mode. Hence, compound **3.12d** could bridge the D₄R-μOR heterodimer.

Unexpectedly, we were unable to identify bivalent ligands that show a biphasic binding mode or a significant increase in affinity for cells expressing both the D₂R and the μOR, compared to cells that only express D₂R. This indicates that none of the bivalent ligands is capable of binding both receptors simultaneously, possibly owing to a suboptimal length or nature of the selected linkers, which, however, were based on the spacers of class A GPCR bivalent ligands. On the other hand it cannot be excluded that subtle differences such as differences in the dissociation rate of the ligands remain undetected by comparing equilibrium dissociation constants. In a study investigating adenosine A₃ receptors, it was found that ligand binding kinetics is found to be influenced in membrane microdomains as a consequence of receptor dimerization.

While future studies may try to address these shortcomings, the current study already gives access to the monomeric ligands that are equipped with appropriate ligation handles to construct second-generation bivalent ligands with alternative spacers. In conclusion, the present results provide useful insights into development of new bivalent ligands as tools to investigate the μOR-D₄R heterodimer.

In order to overcome the above shortcomings, we have designed and synthesized twenty four potential heterobivalent ligands of D₂-likeR and mGluR5 using three different types of linkers, as described in Chapter IV. As depicted in Figure 1, bivalent ligands were derived from the selective and potent noncompetitive mGluR5 antagonist 3-[(2-methyl-4-thiazolyl)ethynyl]pyridine (MTEP). As D₂-likeR ligands we used the previously synthesized antagonist 1,4-DAP and the agonist 5-OH-DPAT with an alkyne ligation handle. Bivalent ligands were built with three different types of spacers of variable length (PEG, polyalkyl and tertiary amine liners) with a primary amine on one and an azide on the other end (Figure 1).

Ligation of D₂-likeR ligands showed that bivalent ligands with PEG (PEG₄ and PEG₆) and hexamethylene linkers exhibit relatively low affinity for D₄R, contrary to bivalent ligands with alkylamine spacers, while all can still activate the D₄R. Interestingly, we identified a bivalent ligand with a 20-atom alkylamine spacer (**4.20a**) that showed 4-fold affinity increase for the D₂R in cells expressing both the D₂R and the mGluR5, compared to cells only expressing D₂R, suggesting that **4.20a** could bridge the D₂R and mGluR5 receptors. On the other hand, ligation of mGluR5 ligands reveals that **4.20a** shows 5-fold higher affinity for D₂R-mGluR5 compared to its corresponding monovalent ligand **4.19a**, which further supports the bridging hypothesis. Furthermore, **4.20a** displays 4- and 7-fold higher potency compared to the monomeric compounds **3.07** and **4.19a** as determined in MAPK-P for D₂R-

mGluR5, respectively. Interestingly, **4.20a** inhibits the forskolin stimulated cAMP formation with a 4-fold higher potency compared to the monovalent agonist **3.07** in the coexpressing cells, indicating that the bivalent binding requires a lower receptor occupation to exert signaling.

Overall, the length and composition of the linker between the two receptor pharmacophores affected binding affinity and potency both at the D₂-likeR and the mGluR5. Compound **4.20a** could be a promising molecular probe to further investigate the protein-protein interaction of D₂-likeR and mGluR5.

To further study the ligand-receptor interaction, we synthesized twelve novel fluorescent mGluR5 ligands based on alkyne functionalized BODIPY fluorophores (Figure 1) that were used to fluorescently label an azido functionalized mGluR5 negative allosteric modulator in a chemoselective manner employing CuAAC reaction. The preliminary biological results indicate that all the fluorescent ligands are capable of binding to the mGluR5 via NanoBRET. Although the saturation assay needs to be optimized, the affinity of compound **5.03** to mGluR5 is modestly higher than that of **5.10**. Therefore, **5.03** could be a promising fluorescent ligand for the further study and an in-depth evaluation is still going on.

In summary, we successfully synthesized the bivalent ligands with different length and composition of spacers to bridge the D₄R- μ OR and D₂R-mGluR5 heterodimers, respectively. Although radioligand binding assays indicate that we did not identify a bivalent ligand with an optimal spacer to bridge the D₂R- μ OR dimer, all tested ligands could still activate or block the signaling pathway as determined in the MAPK-P assay and β -arrestin2 recruitment. In the article on the successful PEG-conjugated bivalent melanocortin ligands, the nature of the ligands (although also targeting class A GPCRs) themselves is also very hydrophilic (such as peptide). Maybe in our case, characterized by two relatively hydrophobic pharmacophores, the PEG-linker is less suitable.

CHAPTER VII

Broader international context, relevance & future perspectives

VII. BROADER INTERNATIONAL CONTEXT, RELEVANCE, AND FUTURE PERSPECTIVES

VII.1. Marketed small-molecule drugs targeting GPCRs

Rhodopsin-like G protein-coupled receptors (12%), ion channels (19%), protein kinases (10%) and nuclear hormone receptors (3%) account for almost half of all human protein drug targets (Figure 1a). Due to the variable number of approved drugs per target family, these privileged target families are responsible for the therapeutic effect of 70% of small-molecule drugs, while 33% of small-molecule drugs modulate GPCRs.[1]

The highly biased distribution in successfully ‘drugged’ protein families is reflected in the biased distribution of bioactivity data in the ChEMBL database when considered at the target class level (Figure 1b). Figure 1b demonstrates that the discovery-phase investment in rhodopsin-like GPCRs has paid off so far, with the proportion of approved drugs being slightly higher than that of compounds in ChEMBL targeting this family.[1]

Figure 1. Major protein families as drug targets.[1] **a.** Distribution of human drug targets by gene family (left pie chart) and distribution by the fraction of drugs targeting those families (right pie chart). **b.** Clinical success of

privileged protein family classes. Distribution of non-approved compounds in ChEMBL 20 (extracted from the medicinal chemistry literature, with bioactivity tested against human protein targets) per family class, and distribution of approved drugs (small molecules and biologics) per human protein family class. 7TM, seven transmembrane family; GPCR, G protein-coupled receptor; LGIC, ligand-gated ion channel; NTPase, nucleoside triphosphatase; VGIC, voltage-gated ion channel.

VII.2. Bivalent ligands: tools par excellence to study receptor dimers

GPCRs are a remarkably multifaceted family of transmembrane proteins that exert a variety of physiological effects. Although family A GPCRs are able to operate as monomers, there is increasing evidence that dimerization (or oligomerization) represents a fundamental aspect of GPCR function, trafficking and pharmacology. Hence, it has been suggested that GPCR dimers may represent crucial new molecular targets for bivalent and/or dimer-selective ligands. Bivalent GPCR ligands are single chemical entities designed to selectively interact with binding sites of two separate GPCRs. The increased interest for targetting GPCR dimers with bivalent ligands stems from the superior potency and safety profiles one may achieve as compared with single target agents. Hitherto, bivalent ligands have been utilized mainly as pharmacological tools to investigate GPCR dimerization *in vitro* and *in vivo* as discussed in Chapter I.2.[2][11]

Gmeiner et al.[103] reported bivalent 1,4-DAP and/or aminoindane ligands with various types of spacers, including PEG, polyalkyl and ferrocene spacers, targeting dopamine receptors.[2-5] Bivalent ligands with an optimal spacer displayed higher Hill slopes than the monomeric ligand **1.20** for the human D_{2short} receptor (see Chapter I Figure 26).

Figure 2. Bivalent D₂R ligands with different kinds of linkers.[5]

As described in chapter I, Portoghese et al.[6][12] synthesized homo- and hetero-bivalent ligands of opioid receptors that exhibited *in vitro* and *in vivo* properties that differ from those of the corresponding monovalent ligands. Their pioneering work demonstrated that spinal administration of bivalent ligands capable of bridging the GPCR dimers, may lead to superior drug candidates for the treatment of chronic, intractable pain.

While successful bivalent ligands have been constructed targeting dopamine or opioid receptor dimers, we are the first to report bivalent ligands targeting heterodimeric dopamine (D_2 -like) and opioid (μ) receptors.[13] Heterodimerization of D_2R - μOR and D_4R - μOR was formerly suggested by co-immunoprecipitation (co-IP) and bioluminescence resonance energy transfer (BRET) studies in mammalian transfected cells, but further substantiated with our newly synthesized bivalent ligands.

Indeed, bivalent ligand **3.12d** (Figure 3) shows a biphasic binding curve for μOR - D_4R and a 170-fold increased “bivalent affinity” for the $D_4R/\mu OR$ heterodimer compared to that for the D_4R . Unfortunately, no bivalent interaction D_2R - μOR dimers seems to take place with any of the synthesized ligands, which warrants further optimization with regard to pharmacophore selection, attachment point, length and nature of the spacer. Furthermore, alternative assays (besides radioactive ligand binding) might be explored to assess if the bivalent D_2R - μOR ligands effectively bridge the GPCR dimers. Together, these results indicate that the D_4R and μOR form heterodimers that could become a new therapeutic targets, e.g. for the treatment of addiction and chronic pain.

Figure 3. Structure of bivalent ligand **3.12d**.

While the group of Portoghese developed bivalent ligands targeting the mGluR5 and μOR heterodimer,[14] we further corroborated the existence of heteromers of mGluR5 and D_2R , which may represent new targets for the treatment of locomotion, neuropsychiatric disorders, and drug addiction. Bivalent ligand **4.20a** (Figure 4), consisting of a mGluR5 negative allosteric modulator (NAM) connected to the previously used D_2R -ligand via a 20-atom alkylamine spacer showed 4-fold increased affinity for the D_2R in cells expressing both the D_2R and the mGluR5, compared to cells singly expressing D_2R . Likewise, it demonstrated significantly higher affinity and potency for D_2R -mGluR5 compared to its monovalent precursor **4.19a**. Interestingly, **4.20a** inhibits the forskolin stimulated cAMP formation with a 4-fold higher potency than the monovalent agonist **3.07** in coexpressing cells, indicating that the bivalent binding requires a lower receptor occupation to exert signaling. Overall, compound **4.20a** could be a promising molecular probe to further investigate the protein-protein interaction of D_2R and mGluR5, e.g. in native tissues.

Figure 4. Structure of bivalent ligand **4.20a**.

VII.3. From bivalent ligands to drug-like compounds targeting dimeric receptors

VII.3.1. Disadvantages of bivalent ligands

The potential of bivalent ligands as possible therapeutics, as opposed to mere pharmacological tools, remains a topic of discussion.[15] Some obvious hurdles exist in the development of bivalent ligands as drugs, including potential absorption, distribution, metabolism, and excretion (ADME) issues, their unlikeliness to cross the blood–brain barrier, and other issues. These issues are related to some general unfavorable physicochemical properties, particularly their high molecular weight, which does not fit Lipinski’s rule of 5 and hence limits the future use of bivalent ligands as potential drugs. Although these barriers seem insurmountable, bivalent ligands may potentially become useful therapeutics by alternative/advanced administration routes, or by converting them into integrated dual acting ligands (see Chapter VII.3.2). More success, however, is expected from “drug-like” compounds that selectively bind and modulate altered binding pockets, which may originate from receptor heteromerization (see Chapter VII.3.3).

VII.3.2. From bivalent ligands to integrated dual acting ligands

A relatively new offshoot from the “classical” bivalent ligands are the so-called integrated dual acting ligands. These molecules are potentially able to interact at two binding sites of a heterodimer simultaneously, possibly resulting in improved subtype selectivity, higher binding affinity, boosted or modified functional activity, and reduced dependence on multiple drug administration regimens.[16]

Figure 5. (left) Schematic representation of a heterobivalent ligand and integrated dual acting ligand consisting of a receptor X and a receptor Y ligand. (right) Schematic examples of a heterobivalent ligand binding to a heterodimer and an integrated dual acting ligand acting at the two orthosteric sites of two different types of receptor monomers.

Jörg et al. pioneered this concept by converting classical heterobivalent ligands consisting the D₂R agonist ropinirole and the A_{2A}R antagonist ZM 241385 into a so-called integrated and more drug-like dual acting ligand (Figure 6), which maintained the potency of the original pharmacophores at both receptors (A_{2A}R and D₂R).[16] Furthermore, preliminary tests suggest that the integrated dual acting ligand is capable of crossing the blood–brain barrier contrary to the original heterobivalent ligands.

Figure 6. An example of the conversion of a “classical” heterobivalent ligand incorporating the pharmacophores ropinirole and ZM 241385 into an integrated dual acting ligands without the tyramine moiety originally present in ZM 241385.

It is noteworthy that the paradigm of “multiple ligand” approach is not new and many of the drugs originating from screening in animal models, were later found to modulate different targets.[17] Notable

examples are the clinically used neuroleptics, which obviously do not obey to the “one-target, one-disease” approach that dominated the pharmaceutical industry for a long time.

VII.3.3. Towards drug-like compounds that selectively activate heterodimeric receptors

Figure 7. Molecular structure of *N*-naphthoyl- β -naltrexamine (NNTA).[18]

While the integrated dual acting ligands described in VII.3.2 still share structural similarities with the monovalent ligands that target both protomers, one step further would be the identification of “monovalent-like” ligands that selectely target heterodimeric receptors. Yekkiralala et al. [19] discovered that *N*-naphthoyl- β -naltrexamine (NNTA) (Figure 7) selectively activates heteromeric μ/κ -opioid receptors in HEK-293 cells. In a competition binding assay using [3 H]diprenorphine, NNTA was found to bind with very high affinity to cells that express μ - (K_i = 0.077 pM) or κ - (K_i = 0.084 pM) opioid receptors. Interestingly, NNTA was found to be a potent antagonist in cells singly expressing μ -opioid receptor, but an exceptionally potent agonist in cells coexpressing μ/κ -opioid receptors. In the mouse tail-flick assay, NNTA exhibited potent antinociceptive activity. Furthermore, it did not produce significant physical dependence in mice. Taken together, this study afforded important proof-of-concept that it is possible to identify small molecules that selectively activate heteromeric receptors. In this particular case this might lead to the development of new potent analgesics with fewer deleterious side effects.

VII.4. Future Perspectives

In this PhD thesis, we successfully designed and synthesized bivalent D_2 -likeR- μ OR and D_2 R-mGluR5 ligands and identified **3.12d** and **4.20a**, which might be used as molecular probes to further investigate D_4 R/ μ OR and D_2 R/mGluR5 heteromers, respectively.

As mentioned before, we observed a biphasic competition binding curve for compound **3.12d** in cells coexpressing D_4 R and μ OR, which is indicative of a bivalent binding mode. To further validate this, we should perform an additional assay to confirm that addition of a μ OR ligand converts the observed

biphasic binding curve to a monophasic curve. Molecular modeling studies could further assist in rationalizing the S.A.R. observed with the different bivalent ligands and assist in optimizing their structure.

In our study on D₂R-mGluR5 bivalent ligands, **4.20a** showed higher affinity and potency in D₂R-mGluR5 coexpressing cells than the corresponding monomeric compounds. However, preliminary data indicate that the poor water-solubility of **4.20a** precludes reliable *in vivo* studies. Hence, the design bivalent D₂R/mGluR5 ligands with enhanced water-solubility is desirable.

Furthermore to further validate the bridging binding mode of bivalent ligands consisting of an agonist and an antagonist described in this thesis, additional assessment of receptor internalization may be the most valuable approach as illustrated by a study of Daniels et al.[20] These authors discovered a bivalent ligand (**7.09**, Figure 8) composed of a μ OR agonist and a δ OR antagonist.

Figure 8. Structures of bivalent ligands (**7.08** and **7.09**), monovalent ligands (**7.05** and **7.07**), and naltrindole (**7.06**).

This bivalent ligand (**7.09**) was shown to inhibit endocytosis of the heteromeric receptors in HEK-293 cells, contrary to **7.08** and monomeric μ OR agonist **7.05**.^[21] The concept is illustrated in Figure 9.

Figure 9. Effect of **7.06** (NTI) on trafficking of μ - δ heterodimer by **7.09**. A cartoon illustrating the effect of delta antagonist on the disruption of bridging protomers in the μ - δ heterodimer.

Also Le Naour et al. assessed the absence of receptor internalization in HEK293 cells for bivalent ligands containing both a μ OR agonist and a CB1 antagonist.[22]

Very recently, Lensing et al. elegantly showed that bivalent ligands may induce biased signaling. They constructed a so-called biased unmatched bivalent ligand (BUmBL) targeting melanocortin receptor homodimers.[23] BUmBLs also consist of an agonist (His-DPhe-Arg-Trp, **7.10**) and an antagonist (His-DNal(2')-Arg-Trp, **7.11**) pharmacophore connected via various spacers. A selected BUmBL of the human melanocortin-4 receptor (hMC4R) exhibited biased agonism. It potently activated cAMP production ($EC_{50} = 1.9\text{--}5.9\text{ nM}$), but minimally stimulated β -arrestin recruitment ($\leq 55\%$ maximum signal at $10\text{ }\mu\text{M}$). From a medicinal chemistry perspective, this example demonstrates that targeting receptor dimers may become an attractive approach to induce biased signaling.

Figure 10. MCR agonist and antagonist pharmacophores and selected linkers used to construct the bivalent MCR ligands. Red amine and green carboxylic acid represent the attachment points for the linkers.

The cartoon below (Figure 11) explains this concept.[23] Monomeric agonists (blue circle) bind both receptors and activate the cAMP as well as the β -arrestin signal transduction pathway (Figure 11A). Homobivalent agonists (blue circle coupled with black spacer) induce similar signaling (Figure 11B). BUMBLs comprising of an agonist (blue) and an antagonist (red) lead to biased signaling by agonizing the cAMP signaling pathway and antagonizing β -arrestin recruitment upon binding to the asymmetrically signaling homodimer (Figure 11C).

Figure 11. A cartoon illustrating the interaction of ligands with asymmetrically signaling melanocortin homodimers.[23]

These results warrant further assessment of the bivalent ligands synthesized in this thesis to induce biased signaling. In Chapter V, we successfully synthesized a series of fluorescent mGluR5 ligands. Preliminary pharmacological evaluation showed that although the saturation assay via NanoBRET needs to be optimized, the affinity of the red-labeled **5.03** to mGluR5 seems modestly higher than that of **5.10**. Therefore, **5.03** could become a promising tool for investigating D₂R-mGluR5 dimerization at the surface of living cells by NanoBRET.

To better understand the receptor-receptor interaction, the classical approaches such as ligand-induced FRET, BRET or biased signaling and internalization studies are warranted to further assess the correlation of bivalent ligands bridging GPCR dimers, as employed for opioid receptors by Portoghese et al.

Finally, the construction of bivalent ligands **7.14** comprising a D₂R agonist and muscarinic M₁ antagonist (Figure 12) is in progress and successful bivalent ligands may be assessed for reducing locomotion symptoms in Parkinson's disease. The above mentioned internalization will be applied to study whether these bivalent ligands can bridge the D₂R/M₁R heterodimers.

Figure 12. Design of bivalent ligands consisting of a D₂R agonist and M₁R antagonist.

Acknowledgements

Dankwoord — Acknowledgements

Here I would like to take this opportunity to thank all people who helped and supported me in the last four years. First of all, I would express my sincere gratitude to my promoter Prof. Serge Van Calenbergh, for providing me an opportunity to carry out my PhD study under his supervision in the Laboratory for Medicinal Chemistry. Thank you, Serge. I still remember the first day when I went to your office. We discussed my PhD research topics and I asked whether it would be possible to evaluate the final compounds by myself. I often cursed myself for asking this question, especially during tough times. But you always supported and encouraged me. Thank you very much, Serge.

Next, I would like to thank my co-promoter Prof. Kathleen Van Craenenbroeck for believing in me and accepting me as her student in the L-GEST-laboratory of toxicology. She taught me how to survive in the tissue culture room, how to use the machines in the lab and how to perform almost all the experiments hand by hand. Thank you so much, Kathleen. In the beginning I only knew some concepts of radioligand binding and functional assays. By joining your laboratory, I learned a lot from you and all the other colleagues. Now I would say proudly I am not only a chemist but also a pharmacologist.

I thank research collaborators, Lakshmi Vasudevan (L-GEST of UGent) for the evaluation of β -arrestin2 recruitment for μ OR; Prof. Francisco Ciruela (University of Barcelona) for assessing the mGluR5 fluorescent ligands by NanoBRET. I also thank Prof. Patrick Vanderheyden (VUB) for fruitfully discussing the radioligand binding assays. I thank Izet for checking the purity of all my final compounds by LC-MS.

I am grateful to colleagues and friends, for being kind and helpful in all aspects. I thank you, Izet, Martijn, Annelies Van Hoeck, Nora, Kiran, Dries, René Chofor, Arno, Joren, Lijun, Fabian, Jonas, Charlotte, Jakob, Yanlin, Cai and Bram from the Laboratory for Medicinal Chemistry and Kamila, Elise (also, thanks for translating summary in Dutch), René Crans, Lakshmi, An, Karen, Annelies Cannaert, Jolien and Prof. Christophe Stove from the L-GEST-Laboratory of Toxicology.

I am deeply thankful to all my family members, for their affection, encouragement and advices at all times. I thank all those, who contributed in their own way during these years of my life.

Finally, I would thank China Scholarship Council (CSC) for financially supporting my PhD study at UGent.

- ❖ 54th International Conference on Medicinal Chemistry (RICT 2018, Interfacing Chemical Biology and Drug Discovery)

Strasbourg, France, July 4-6, 2018

Poster presentation: Biological evaluation of novel bivalent ligands targeting the dopamine D₂ and metabotropic glutamate 5 receptors

- ❖ 28th Conference of European Comparative Endocrinologists

Leuven, Belgium, August 21-25, 2016

Poster presentation: Biological evaluation of bivalent ligands for dopamine D₂-like receptors and the μ opioid receptor

- ❖ 13th Chemistry Conference for Young Scientists (ChemCYS)

Blankenberge, Belgium, March 16-18, 2016

Poster presentation: Study of the cross-talk between the dopamine D₂-like receptors and the μ opioid receptor

- ❖ Annual One-Day Meeting on Medicinal Chemistry of SRC & KVCV (MedChem 2014)

Braine-L'Alleud, Belgium, November 21, 2014

- ❖ Mini-Symposium ADME Profiling

Leuven, Belgium, March 12, 2014

- ❖ Chemistry Conference for Young Scientists (ChemCYS)

Blankenberge, Belgium, February 27-28, 2014

Overview of synthesized compounds
