18 **Abstract**

19 Low-moisture part-skim (LMPS) Mozzarella cheeses were held at 4°C for 0, 2 or 8 d before
20 freezing to -20°C. The cheeses were frozen at a rate of 0.6, 2.0 or 8.0°C h⁻¹ and held frozen at -
21 20°C for 1, 6, 12 or 44 weeks. After freezing, cheeses were stored at 4°C for 16-37 d, resulting in
22 a total storage time at 4°C (before and after freezing) of 24-37 d (frozen-thawed Mozzarella).
23 Control Mozzarella was stored at 4°C for 25-37 d. The control and frozen-thawed cheeses were
24 assayed for composition, primary proteolysis, moisture distribution, texture profile analysis and
25 melting characteristics after similar storage times at 4°C. Freezing under the evaluated conditions
26 resulted in reduced firmness of the unheated cheese but did not significantly affect the properties
27 of the heated cheese. The results suggest that freezing may be effectively applied to control or
28 extend the functional shelf-life of LMPS Mozzarella shipped to long-distance markets.

29 **1. Introduction**

30 The production of low-moisture part-skim (LMPS) Mozzarella has grown worldwide because of
31 the increasing popularity of pizza. It is a stretched-curd (pasta-filata) cheese, the manufacture of
32 which typically involves kneading and stretching the fermented curd in hot water or dilute brine
33 until it acquires a uniform molten stretchy consistency. The plasticization process confers the
34 cheese with the ability to stretch and undergo limited oiling-off when subsequently baked on pizza
35 (McMahon & Oberg, 2017). Based on the author's knowledge of the South-East Asian market,
36 some producers import LMPS Mozzarella from Europe, the United States, Australia and/or New
37 Zealand to compensate issues with local milk quality and supply. Guinee, Mulholland, Mullins,
38 Corcoran & Auty (1999) reported that extended storage of LMPS Mozzarella (e.g. > 60 d at 4°C)
39 resulted in a deterioration in functionality as manifested by the shredded cheese developing an
40 increased susceptibility to clumping/balling and the baked cheese exuding excess free oil, and
41 having a 'soupy' consistency to a degree dependent on cheese composition and proteolysis. Bertola,
42 Califano, Bevilacqua & Zaritzky (1996a) noted that producers freeze LMPS Mozzarella for long-
43 distance export to minimize changes in proteolysis and functionality. Relatively few studies have
44 investigated the effects of freezing on the physicochemical and functional characteristics of LMPS
45 Mozzarella. Ribero, Rubiolo & Zorilla (2007) reported that the freezing point of LMPS Mozzarella
46 ranged between -1.2°C and -2.6°C owing to the presence of solutes (i.e., salts, minerals, N-soluble
47 compounds, lactose and organic acids) in the serum phase. Some studies investigated the effects of
48 freezing on the mechanical characteristics of LMPS Mozzarella (Cervantes, Lund, & Olson, 1983),
49 but did not evaluate other characteristics such as extensibility, consistency and flow of the cooked
50 cheese, which are critical functionalities in pizza application. Potential issues with the freezing of
51 cheese include ice crystallization in the serum phase, mineral deposition, casein dehydration and

52 thereby impairment of the functionality of the frozen-thawed cheese (Everett & Auty, 2008; Kuo
53 & Gunasekaran, 2003; Oberg, Merrill, Brown, & Richardson, 1992). Kuo, Anderson &
54 Gunasekaran (2003) monitored the formation of ice crystals in small LMPS Mozzarella plugs (504
55 mm³), exposed to cold air at -40°C, using magnetic resonance imaging (MRI) and found that
56 freezing proceeded symmetrically with the nucleation of ice crystals starting from the outside and
57 progressing inwards during further cooling. The effects of freezing Mozzarella cheeses (5 x 10 x 7
58 cm) at -20°C on the para-casein matrix were determined using nuclear magnetic resonance (NMR)
59 (Kuo et al., 2003) and scanning electron microscopy in a subsequent study (Kuo & Gunasekaran,
60 2009). The authors observed a ruptured para-casein network in frozen-thawed Mozzarella and
61 suggested that formation of large ice crystals or recrystallization of ice crystals during frozen
62 storage could potentially weaken the ability of the para-casein matrix to retain moisture, increase
63 serum leakage after thawing, and reduce the melt and stretch of the baked cheese. Kuo &
64 Gunasekaran (2003) noted that the changes in protein structure, and thereby the changes in
65 functionality, could be limited by ripening LMPS Mozzarella before freezing or partially restored
66 by ripening LMPS Mozzarella after thawing. According to Bertola et al. (1996a), LMPS
67 Mozzarella could be frozen without loss of quality provided that the combined storage time of the
68 cheese before and after freezing ranged from 14 to 21 d. These findings suggested that the duration
69 of storage, and hence the level of proteolysis and water binding by the para-casein network of the
70 cheese, is a critical mediator of functionality and should be tightly controlled when freezing LPMS
71 mozzarella to normalize functional performance. Also, the freezing rate could be controlled to limit
72 the size of the formed ice crystals. Bunker (2016) investigated the effects of the freezing rate,
73 expressed as the time to freeze the center of 4 mm thick cheese slabs to -18°C, on LMPS Mozzarella.
74 The author found that the meltability of the cheese, measured by small-strain oscillation rheology
75 and expressed as the maximum loss tangent upon heating the cheese to 100°C, decreased when the

76 time-to-freeze increased from 0 minutes to 95 minutes. In addition, serum relocation from the
77 center of the cheese to its surface was higher when cheeses were frozen to -18°C in 95 minutes as
78 compared to 0 minutes. Conversely, Bertola et al. (1996a) reported that freezing rate, which was
79 defined as the time for the temperature of cheese blocks placed at -20°C to decrease from -1.1 to
80 6.7°C (0.22 or 10 h), had no effects on LMPS Mozzarella. The inter-study discrepancy on the
81 impact of freezing may be related to differences in Mozzarella composition or freezing conditions.
82 The current study reports on the effects of freezing and key freezing conditions, including freezing
83 rate (FR), storage time in the freezer (TIF) and storage time at 4°C before freezing (TBF), on the
84 properties of commercial LMPS Mozzarella, including proteolysis, ratios of soluble-to-total
85 calcium and mobile serum-to-total serum, and functionality. The effects of freezing on these
86 parameters in LMPS Mozzarella have not been clearly exemplified in literature despite of the fact
87 that they are strongly related to textural, viscoelastic, stretch or melt properties (Banville, Morin,
88 Pouliot, & Britten, 2013; Feeney, Fox, & Guinee, 2001; Guinee, Feeney, Auty, & Fox, 2002; Imm,
89 Oh, Han, Oh, Park & Kim, 2003; Smith, Hindmarsh, Carr, Golding, & Reid, 2017).

90 **2. Materials and methods**

91 **2.1. Cheese treatments**

92 LMPS Mozzarella cheeses (2.5kg; 28 cm x 10 cm x 8 cm) were supplied by Milcobel cvba
93 (Langemark, Belgium). Seven cheese vats (A, B, C, D, E, F and G) were sampled over the span of
94 1.5 years to take the variability in milk composition and cheese processing into account. For each
95 cheese vat sampled, consecutive cheese blocks were removed from the production line, such that
96 the sampled blocks corresponded to the curd from the middle of the cheese vat. This was chosen
97 to minimize the inter-block variability between cheeses taken from the vat. After sampling, the
98 cheeses were sealed in plastic vacuum bags, placed at 4°C and assigned to various treatments:
99 control cheeses which were stored at 4°C for up to 37 d, and frozen-thawed cheeses, which were

100 held at 4°C for 0, 2 or 8 d and frozen to -20°C at different rates (0.6, 2.0 or 8.0°C h⁻¹). The frozen
101 cheeses were held at -20°C for 1, 6, 12 or 44 weeks, and placed at 4°C for a period of 16-37 d. All
102 cheeses were transported chilled to the laboratory (Teagasc, Food Research Centre, Ireland and
103 Ghent University, Belgium), where the characteristics of control and frozen-thawed cheeses were
104 compared after 3 different storage times at 4°C to determine the effects of freezing, storage and
105 possible interaction-effects.

106 **2.1.1. Frozen-thawed LMPS Mozzarella**

107 The effects of the following freezing conditions were investigated as treatments: freezing rate (FR),
108 time in freezer at -20°C (TIF) and storage time at 4°C before freezing (TBF). The various
109 treatments are described in Tables 1, 2 and 3, respectively, and are discussed in detail below. For
110 each treatment, analyses were performed on 2 cheeses at each storage time at 4°C.

111 **2.1.1.1. Effects of the freezing rate (FR)**

112 Twenty-four cheeses were taken from cheese vat A (Table 1). Six cheeses were stored at 4°C and
113 analyzed at 4, 15 or 37 d (control). Eighteen cheeses were held at 4°C for 0 d before freezing to -
114 20°C. To simulate different cooling rates, 6 cheeses were transferred into a Styrofoam box placed
115 in a chest freezer at -20°C (coded M1), 6 cheeses were placed individually in a chest freezer at -
116 20°C (coded M2), and 6 cheeses were transferred into a freezing room at -40°C for 2 hours after
117 which they were transferred to a chest freezer at -20°C (coded M3). Freeze-resistant thermocouples
118 (176T3, Testo, Ternat, Belgium) were used to monitor the temperature at the core and surface of
119 the cheese blocks, and to ensure that the temperature of cheeses placed at -40°C did not decrease
120 to less than -20°C. M1, M2 and M3 resulted in cooling rates of 0.6°C (FR0.6), 2.0°C (FR2.0) and
121 8.0°C h⁻¹ (FR8.0), respectively, as derived from the slope of the cooling curve between the start of
122 cooling and the onset of freezing (i.e., point where latent heat of crystallization became visible).
123 The cheeses were held frozen for 6 weeks, after which they were placed at 4°C and analyzed after

124 total storage times at 4°C of 4, 12 or 37 d (Supplement A, Cheese vat A). The effects of FR were
125 determined by comparing cheeses with different FR after similar total storage times at 4°C, while
126 the effects of freezing were determined by comparing each FR cheese with the corresponding
127 control cheeses after similar total storage times at 4°C. Total storage time is defined as the
128 cumulative time for which the cheese was held at 4°C before analysis, i.e., the sum of storage times
129 at 4°C before and after freezing.

130 **2.1.1.2. Effects of the time in freezer (TIF)**

131 Following manufacture, 40 cheeses were sampled from cheese vat C (Table 2). Eight cheeses were
132 stored at 4°C and analyzed after 4, 10, 16 or 30 d (control). Thirty-two cheeses were held for 2 d
133 at 4°C and transferred to a chest freezer at -20°C. The TIF was varied by holding the cheeses frozen
134 for 1 (TIF1), 6 (TIF6), 12 (TIF12) or 44 weeks (TIF44). After freezing, cheeses were placed at 4°C
135 and analyzed after total storage times at 4°C of 4, 10, 16 or 30 d (Supplement A, Cheese vat C).
136 The effects of TIF were determined by comparing cheeses with different TIF after similar total
137 storage times at 4°C, while the effects of freezing were determined by comparing each TIF cheese
138 with the corresponding control cheeses after similar total storage times at 4°C.

139 **2.1.1.3. Effects of the storage time before freezing (TBF)**

140 The TBF was varied by holding LMPS Mozzarella cheeses at 4°C for 0, 2 or 8 d before transferring
141 to a chest freezer at -20°C (Table 3). The effects of TBF were evaluated following a between-
142 subjects design (i.e., cheese of different vats was subjected to one TBF condition) (Supplement A).
143 This approach ensured a similar sample size for each TBF condition, i.e., 24 cheeses with a TBF
144 of 0 d from vats A and B, 32 cheeses with a TBF of 2 d from vat C and 24 cheeses with a TBF of
145 8 d from vats D, E, F and G. Samples from vats B, D, E, F and G were held frozen for a period of
146 1 week - 6 weeks. After freezing, all cheeses were placed at 4°C and analyzed after different storage
147 times. The effects of freezing at different TBF were determined by comparing the corresponding

148 control cheeses with each of the TBF treatments after similar storage times at 4°C. Two cheese
149 blocks from each treatment (control and TBF) were compared after each storage time at 4°C.

150 **2.2. Experimental analysis**

151 **2.2.1. Cheese sampling**

152 Cheese blocks were divided into four symmetrical quarters by cutting halfway along the length and
153 width. One quarter was shredded (Robot Coupe CL50, shredding disc, aperture 5mm, Voor 't Labo
154 CVBA, Eeklo, Belgium) and grated to a particle size of < 1 mm (Food Processor Russell Hobbs,
155 Spectrum Brands Europe GmbH, Sulzbach, Germany). Grated cheese was used for the analysis of
156 composition, soluble calcium and pH 4.6 soluble N. A second quarter was used to prepare six cube
157 samples (25 mm ± 1 mm) (Cheese Blocker, Bos Kaasgereedschap, Boven graven, the Netherlands)
158 for texture profile analysis. The cubes were wrapped tightly in aluminum foil and stored at 4°C for
159 4 h prior to analysis. A third quarter was shredded, stored at 4°C for ~1 d and used for measurement
160 of cheese extensibility. The fourth cheese quarter was used to prepare samples for small strain
161 oscillation rheology (2 discs: 50 mm diameter, 2 mm thick) and flow of the heated cheese by the
162 Schreiber-based test (4 discs: 45 mm in diameter, 4 mm thick).

163 **2.2.2. Cheese composition**

164 Grated LMPS Mozzarella was analyzed for moisture, total nitrogen (N), salt and total calcium
165 content in duplicate using International Dairy Federation standard methods as described by Guinee,
166 Auty & Fenelon (2000). The pH was measured on a cheese slurry prepared from 20 g of cheese
167 and 12 g H₂O after 2 d of storage at 4°C (Guinee et al., 2000). Fat was determined by nuclear
168 magnetic resonance (NMR) (Smart Turbo, CEM Corporation, Matthews, North Carolina, USA).

169 **2.2.3. Soluble calcium and pH 4.6 Soluble N (pH4.6SN)**

170 A water-soluble extract (WSE) of the cheese was prepared by blending distilled water (50°C) and
171 grated cheese at a weight ratio of 2:1 (Stomacher, Lab-Blender 400; Seward Medical, London, UK)
172 for 5 min, holding at 50°C for 1 h, centrifuging at 3000 g for 20 min at 4°C (Sorvall LYNX 6000
173 Superspeed centrifuge, Thermo Scientific, Dublin, Ireland), and filtering through glass wool (Acros
174 organics, Geel, Belgium). A portion (4 mL) of filtrate (WSE) was ashed at 550°C and the ash was
175 analyzed for calcium by flame atomic absorption spectroscopy (ISO 8070, IDF 119:2007). Serum-
176 soluble calcium was expressed as a percentage of the total cheese calcium content. A further portion
177 (60 ml) of the WSE was adjusted to pH 4.6 using 10% w/w HCl (Honeywell Fluka™ Chemicals,
178 Offenbach, Germany), centrifuged at 3000 g for 20 minutes at 4°C and filtered through glass wool.
179 The resultant pH 4.6 soluble filtrate was analyzed for N using the macro-Kjeldahl method (ISO
180 8968-1:2014, IDF 20-1:2014) and expressed as a percentage of total cheese nitrogen.
181 Measurements were performed in duplicate per cheese.

182 **2.2.4. Time domain ¹H NMR relaxometry**

183 The T₂ relaxation time distribution of LMPS Mozzarella was evaluated by low-field NMR on a
184 benchtop Maran Ultra spectrometer (Oxford instruments, Abingdon, UK), operating at 0.55T (23.4
185 MHz for ¹H). The method was described by Vermeir, Declerck, To, Kerkaert & Van der Meeren
186 (2019) who distinguished three serum fractions comprising liquid oil protons and water protons in
187 LMPS Mozzarella with different T₂ relaxation times (i.e., the time at which the magnetization
188 signal decays to 37% of its original value). The serum fraction characterized with the longest
189 relaxation time was ascribed to weakly interacting serum protons and could be interpreted as ‘more-
190 mobile-serum’. In this study, the relative signal intensity of the more-mobile-serum fraction (A_{60ms}),
191 measured as the ratio of the integrated signal area of the ‘more-mobile-serum’ fraction to the total
192 integrated signal area of all serum fractions, was reported. The latter ratio is indicative of serum
193 that is not immobilized by the calcium-phosphate para-casein network of the cheese, and is

194 therefore available for freezing; hence, cheese with a lower A_{60m} is less likely to be impaired by
195 freezing (Kuo et al., 2003). Relaxometry measurements were performed in one TBF0 and one
196 TBF8 experiment, owing to the constraints of analytical time and equipment availability. Triplicate
197 measurements were performed at two separate locations in one Mozzarella block after 0, 1, 2, 4, 8
198 or 16 d storage at 4°C. To report the overall effects of freezing on serum behavior, we included the
199 data as an observation only as the measurements were not included in each freezing experiment.

200 **2.2.5. Texture profile analysis (TPA)**

201 Cheese cubes were taken individually from the refrigerator and loaded on a TAHDi texture analyzer
202 fitted with a 100 kg load cell (Stable Micro Systems, Goldalming, UK). Each cube was compressed
203 in two consecutive bites at a speed of 1 mm s⁻¹ to 60% of its original height. The method was based
204 on the method applied by Guinee, Pudja, Miocinovic, Wiley & Mullins (2015). The following
205 parameters were derived from the resultant time-force curve: maximum compression force
206 recorded during bite 1 (firmness), the ratio of height to which the cube was compressed at the start
207 of bite 2 relative to the sample's original height (springiness), the ratio of work required to
208 compress the cube in bite 2 relative to that of bite 1 (cohesiveness) and the product of firmness x
209 springiness x cohesiveness (chewiness). Measurements were performed in sextuplicate per cheese.

210 **2.2.6. Extension work (EW)**

211 EW was evaluated by a modification of the method described by Guinee et al. (2015). Shredded
212 cheese (60 g) was weighed in a heat resistant vessel (Stable Micro Systems, Goldalming, U.K.)
213 and heated in a microwave oven (Whirlpool MW201, Fonthill Industrial Estate, Dublin, Ireland)
214 set at 750 W for 60s until the cheese temperature was 85 to 95°C. The vessel containing the heated
215 cheese was then loaded on a TAHDi texture analyzer (Stable Micro Systems, Goldalming, UK)
216 and uniaxially extended at a rate of 10 mm s⁻¹ to a height of 380 mm. EW was defined as the

217 cumulative work required to extend the hot molten cheese, directly after heating (EW_0) and after
218 allowing the cheese to cool down for 5 minutes at room temperature (EW_5); EW_5 was used to
219 simulate the impact of cooling-induced stiffening of molten cheese on a pizza during consumption.
220 EW_0 and EW_5 were measured in triplicate and in duplicate, respectively.

221 **2.2.7. Small strain oscillation rheology**

222 Heat-induced changes in viscoelastic characteristics, including storage modulus, G' , loss modulus,
223 G'' , and loss tangent, G''/G' , on heating from 25°C to 90°C were measured using low amplitude
224 strain oscillation rheology on a strain-controlled rheometer (MCR501, Anton Paar GmbH, Graz,
225 Austria) (Guinee et al., 2015). Cheese discs (50 mm diameter; 2 mm thickness) were prepared and
226 placed between parallel cross-hatched plates (PP50/P2-SN27902; [diameter = 50 mm]; INSET I-
227 PP50/SS/P2). The exposed surface of the cheese disc was brushed with a thin layer of silicone oil
228 (silicone oil, Sigma-Aldrich, Arklow, Ireland) to prevent surface dehydration during measurement.
229 Samples were equilibrated at 25°C for 15 minutes and subjected to a low amplitude shear strain (γ
230 = 0.0063) at an angular frequency of 1 Hz, and the temperature was increased from 25°C to 90°C
231 at a rate of 3.25°C min⁻¹. The cross-over temperature (COT), corresponding to the temperature at
232 which $G' = G''$ (i.e., the point at which the solid index of the sample was equal to its liquid index
233 or the point at which the cheese transitioned from the solid phase into the liquid phase) and the
234 maximum value of loss tangent (LT_{max}) (i.e., an index for the fluidity of the cheese during heating)
235 were reported. Measurements were performed in duplicate.

236 **2.2.8. Schreiber flow**

237 Cheese discs (45 mm diameter; 4 mm thickness) were placed on circular glass dishes, heated at
238 280°C for 4 minutes in a convection oven (Binder FD 35, Binder GmbH, Tuttlingen, Germany),
239 removed, allowed to cool at room temperature for 30 min and measured for length along 4

240 equidistant diagonals. Flow was defined as the percentage increase in mean diameter during heating.
241 Measurements were performed in quadruplicate.

242 **2.2.9. Baking test**

243 Frozen pizza bases (25 cm diameter) with tomato paste (Bladerdeeg Van Marcke, Belgium) were
244 thawed for 3 hours at room temperature. Control (75g) and frozen-thawed Mozzarella (75g) shreds
245 were each spread uniformly on opposite halves of the base and baked at 245°C for 5.25 min in a
246 conveyor oven (Lincoln Impinger, Fort Wayne, IN, USA). Following baking, the attributes ‘blister
247 color’, ‘blister coverage’, ‘meltability’, ‘oiling off’, ‘stretch’, ‘first chew’ and ‘chewiness’ were
248 scored sequentially by trained laboratory personnel at Milcobel. A score of 2 was awarded if the
249 characteristic was ‘just right’, a score of < 2 was given when the attribute was subpar, and a score >
250 2 was given if the attribute was more strongly present. Scores of 0 or 4 implied that the measured
251 characteristic was unacceptable because the level of the attribute was either too little or too high,
252 respectively. ‘Blister color’ was indicative of color intensity of the blisters, which ranged from
253 light brown to black, and ‘blister coverage/density’ of the proportion of pizza surface covered by
254 blisters. ‘Meltability’ was a measure of how well the cheese shreds were fused together after baking.
255 ‘Meltability’ scores of < 2 were awarded where individual shreds were visible after baking, while
256 scores > 2 were given where cheese was runny. ‘Oiling off’ was a measure of the amount of oil
257 released as a film on top of the pizza after baking. ‘Stretch’ was manually evaluated by lifting
258 cheese from the baked pizza surface using a fork and extending to a maximum height of 30 cm.
259 ‘First chew’ and ‘chewiness’ were evaluated by tasting a forkful of the molten Mozzarella. ‘First
260 chew’ was a measure of the resistance perceived during the first bite, while ‘chewiness’ coincided
261 with toughness perceived during overall mastication, as moisture and oil were continuously
262 released from the protein matrix.

263 **2.3. Statistical analysis**

264 A factorial design incorporating two factors, A (cheese treatment) and B (total storage time at 4°C),
265 was used for the analysis of response variables. The main effects of A and B and their interaction
266 effect, A x B, on each response variable was determined separately using two-way analysis of
267 variance. Main effects were compared pair-wise using the Least Significant Difference (LSD) test.
268 In presence of significant interaction effects, a simple main effects analysis, which determines the
269 effects of cheese treatments at each level of the storage time at 4°C, was used. To determine
270 treatment impact on sensory properties, a Kruskal-Wallis test was performed. The level of
271 significance was determined at $\alpha = 0.05$ throughout. This approach was used to determine the
272 overall effects of freezing and storage time at 4°C on response variables. The effects of specific
273 freezing conditions (e.g., FR, TIF and TBF) were determined likewise.

274 **3. Results and discussion**

275 **3.1. Cheese composition**

276 The mean compositions of the cheeses used for comparing the different treatments are given in
277 Table 4. Slight but significant inter-vat differences were found in dry matter, fat, salt, calcium
278 content and pH. This indicated that determining the effects of TBF, which involved cheeses from
279 different vats, may have been somewhat confounded by such compositional variation. The effects
280 of FR and TIF were not affected by inter-vat compositional variation in cheese as cheeses for each
281 of these treatments were taken from the same vat.

282 **3.2. Overall changes during storage at 4°C of LMPS Mozzarella**

283 The overall comparisons between control and frozen-thawed cheeses, frozen under different
284 conditions, are presented in Fig. 1 and Fig. 2. Each response variable is categorized by two factors:
285 ‘cheese treatment’ (control or frozen-thawed cheese) and ‘storage time at 4°C’. The values
286 presented for frozen-thawed cheeses at the different storage times are means of cheeses frozen
287 under different FR, TIF or TBF conditions. First, the interaction-effects between ‘cheese treatment’

288 and 'total storage time at 4°C' were determined (Table 5). For each response variable, where no
289 significant interaction-effect could be demonstrated, the effect of cheese treatment was determined
290 by comparing the mean values of control cheeses with those of frozen-thawed cheeses, while
291 keeping the factor 'storage time at 4°C' fixed. Likewise, the effects of storage time at 4°C were
292 determined by comparing the mean values between the different storage times, while keeping the
293 factor 'cheese treatment' fixed. If a significant interaction effect was found, the effect of cheese
294 treatment was determined at each storage time separately.

295 3.2.1. Physicochemical changes during storage at 4°C

296 Both the control and frozen-thawed cheeses exhibited a reduction in more-mobile-serum fraction
297 (Fig. 1A) and an increase in less-mobile-serum fraction during storage at 4°C (Fig. 1B). This
298 indicated that the more-mobile-serum was gradually 'immobilized' during storage at 4°C owing to
299 its uptake into the para-casein network of the cheese matrix. This trend is consistent with the
300 reduction in expressible serum during the storage of LMPS Mozzarella (McMahon and Oberg,
301 2017). Similarly, proteolysis increased progressively in all cheeses on storage at 4°C, as evidenced
302 by the linear increase in pH4.6SN (Fig. 1C). The proximity of dashed trend lines for pH4.6SN of
303 the control and frozen thawed cheeses showed that freezing had no effect on primary proteolysis.
304 A different trend was reported by Bertola et al. (1996b) for concentration of 12% trichloroacetic
305 acid soluble N (TCAN) in low-moisture Mozzarella, whereby cheeses stored for 6 d at 4°C before
306 freezing at -20°C had higher values than the refrigerated control cheeses at similar storage times.
307 However, in the same study, storage of the cheese for 14 d at 4°C before freezing resulted in similar
308 TCAN values as the control cheeses. The relatively low values of pH4.6SN for all cheeses, for
309 example compared to Cheddar cheese, were consistent with those reported previously for LMPS
310 Mozzarella and reflected the high degree of chymosin inactivation during plasticization (Feeney et

311 al., 2001). The ratio of soluble-to-total Ca varied from 30% to 45% (Fig. 1D) and was not affected
312 by storage time at 4°C or freezing ($P > 0.05$) (Table 5).

313 Some studies postulated that freezing could affect the behavior of LMPS Mozzarella owing to
314 protein dehydration concurrent with the formation of ice crystals at the exterior of the Mozzarella
315 cheese, which would promote serum relocation from the core to the exterior of the cheese block
316 (Bunker, 2016; Kuo & Gunasekaran, 2003). Moreover, it would be feasible to assume that
317 precipitation of calcium phosphate by migration of soluble Ca and P to the unfrozen serum may
318 further contribute to para-casein aggregation and thereby reduce the susceptibility to proteolysis
319 (Fox, 1970). However, the current results showed that for the current LMPS Mozzarella cheeses,
320 freezing halted storage-related changes in serum distribution (not statistically verified) and
321 pH4.6SN, and did not influence their levels in the frozen-thawed LMPS Mozzarella ($P > 0.05$). It
322 is likely that variation in the composition (e.g., moisture content, calcium and pH) and proteolysis
323 of different commercial Mozzarella cheese variant may alter the susceptibility to freezing.

324 3.2.2. Functional characteristics during storage at 4°C

325 Increasing storage time of control and frozen-thawed cheeses resulted in lower values of cheese
326 firmness (Fig. 2A), COT (Fig. 2B) and EW (Fig. 2D and Fig. 2E), and higher values of LT_{max} (Fig.
327 2C) and flow (Fig. 2F). These changes are consistent with the increase in pH4.6SN and the
328 reduction in more-mobile serum (A_{60ms}) during storage at 4°C (Guinee et al., 2002).

329 Overall, no significant interaction effects could be demonstrated between ‘cheese treatment’ and
330 ‘storage time at 4°C’ for most of the response variables, including firmness of the unheated cheese
331 ($P > 0.05$), and extensibility (EW_0 , EW_5) ($P > 0.05$) and viscoelastic properties (COT, LT_{max}) ($P >$
332 0.05) of the heated cheese (Table 5), which indicated that the rate of storage-related changes of
333 these characteristics at 4°C was similar for the control and frozen-thawed cheeses, as illustrated in
334 Fig. 2. After freezing and thawing, the firmness and chewiness of the unheated cheeses were

335 significantly reduced by 10% and 8%, respectively ($P < 0.001$) (Table 5). However, some studies
336 (Alvarenga, Canada, & Sousa, 2011; Bertola, Califano, Bevilacqua & Zaritzky 1996b) reported
337 that frozen-thawed LMPS Mozzarella had a higher firmness than the corresponding cold-stored
338 cheeses, whereas Cervantes et al. (1983) found that the firmness was unaffected by freezing. No
339 effect of freezing was found for either the cohesiveness ($P > 0.05$) and springiness ($P > 0.05$) of
340 the unheated cheeses, or the extensibility (EW_0 , EW_5) ($P > 0.05$) or viscoelastic properties (COT,
341 LT_{max} ,) ($P > 0.05$) of the heated cheese. A significant interaction ($P = 0.019$) was found for
342 Schreiber flow, as illustrated by Fig. 2f where it can be seen that the effects of freezing, relative to
343 the control, depended on the storage time at 4°C. Hence, the effect of freezing on the flow of the
344 heated cheeses was determined at each level of the storage time but no differences could be
345 demonstrated between control and frozen-thawed cheeses ($P > 0.05$).

346 3.2.3. Baking characteristics during storage at 4°C

347 No clear differences were detected between the control and frozen-thawed cheeses for ‘blister
348 color’, ‘blister coverage’, ‘meltability’, ‘oiling off’, ‘stretch’ and ‘chewiness’ ($P > 0.05$) after
349 baking on a pizza (Fig. 3). However, the ‘first chew’ of frozen-thawed cheeses received a score of
350 0.3 units less than that of the corresponding control cheeses after a total storage time at 4°C at 16
351 d ($P < 0.05$), which suggested that freezing resulted in a slightly softer ‘first chew’. This trend was
352 consistent with the reduction in firmness and chewiness of the unheated cheese after freezing and
353 thawing, as measured by TPA. However, no effects of freezing on the attribute ‘first chew’ could
354 be demonstrated at other storage times.

355 3.3. Effects of specific freezing conditions

356 It is possible that the overall effects of freezing, as discussed in Section 3.2, may have been
357 obscured by the effects of specific freezing conditions with opposite effects. Hence, the effects of

358 each of the freezing conditions, i.e., FR, TIF and TBF, were investigated separately and are
359 discussed in detail below.

360 **3.3.1. Effects of freezing rate (FR)**

361 LMPS Mozzarella is commercially frozen in palletized format by placing them in large freezing
362 rooms operating at -20°C . The low heat conductivity of Mozzarella (Dumas & Mittal, 2002),
363 however, results in non-uniform cooling of the pallet with temperatures dropping quickly at the
364 exterior of the pallet and slowly at the core. Mozzarella cheeses were frozen at a rate of 2°C h^{-1}
365 (i.e., individual cheeses placed in a chest freezer at -20°C) or $0.6^{\circ}\text{C h}^{-1}$ (i.e., individual cheeses
366 placed in a Styrofoam box in a chest freezer at -20°C) to simulate the freezing of LMPS Mozzarella
367 blocks in the exterior and interior portions of palletized cheese, respectively, when placed at -20°C .
368 Cheeses were also frozen at a rate of 8°C h^{-1} to investigate the effects of a faster freezing method
369 (e.g., tunnel freezing).

370 The statistical significance (P) for the effects of freezing at different freezing rates, storage time at
371 4°C , and their interaction on the properties of Mozzarella is shown in Table 6. No interaction effect
372 between the cheese treatments and storage time at 4°C could be demonstrated for most response
373 variables. The more-mobile-serum fraction ($A_{60\text{ms}}$) of frozen-thawed samples decreased from 4%
374 to 0% during storage at 4°C , and was not affected by the freezing rate ($P < 0.05$). As such, the
375 storage-related changes in more-mobile-serum fraction, i.e. its uptake in the calcium-phosphate
376 para-casein network during storage at 4°C , were similar for all freezing rates. Likewise, the
377 proportion of soluble-to-total calcium, which varied from 31% to 36% during storage, and
378 pH4.6SN were unaffected by the freezing rate ($P > 0.05$). The obtained results further showed no
379 effects of freezing rate on the firmness of the unheated cheese ($P > 0.05$), or the extensibility (EW_0 ,
380 EW_5) ($P > 0.05$), viscoelastic properties (COT , LT_{max}) ($P > 0.05$) or sensory attributes of the heated
381 cheese ($P > 0.05$). However, a significant interaction was found for the flow of the cheeses, as

382 measured by the Schreiber test. After 4 d storage at 4°C (storage time 1, Table 6), frozen-thawed
383 cheeses subjected to freezing rates 2.0°C h⁻¹ or 8.0°C h⁻¹ had a mean flow of 36-38% upon heating
384 for 4 min at 280°C whereas cheese frozen at a rate of 0.6°C h⁻¹ had a flow of 47%. At storage times
385 of 12 d (storage time 2, Table 6), flow plateaued at ~45-48% for all freezing rates. Overall, the
386 results indicated that the FR did not significantly influence storage-related changes in moisture
387 redistribution, primary proteolysis or functional characteristics. Similar conclusions were found for
388 the measured variables of control and frozen-thawed cheeses frozen at different freezing rates.
389 Potentially, the freezable serum of the current LMPS Mozzarella cheese was too limited to induce
390 an effect of freezing, even when cheeses were frozen directly after production and packaging.

391 **3.3.2. Effects of time in freezer (TIF)**

392 After manufacture and freezing of LMPS Mozzarella, the duration of frozen storage depends on
393 various commercial factors including the dispatch time (i.e., released from the producer to the
394 distributor or harbor), the loading time (i.e., loading of Mozzarella on the ship), the transportation
395 time on the boat, the docking time (i.e., release of Mozzarella at the harbor of the country of
396 destination), the transportation time to the customer and the storage time at -20°C at the customer.
397 To simulate these conditions, LMPS Mozzarella was held at 4°C for 2 d before freezing to -20°C
398 and stored frozen for 6 to 12 (TIF6 and TIF12) weeks to mimic the duration of frozen export, and
399 for 44 weeks (TIF44) to simulate the duration of long-term frozen storage as applied by some
400 customers who on receipt of frozen Mozzarella maintain it frozen for a relatively long time prior
401 to thawing and using. Cheeses were also kept frozen for 1 week (TIF1) to evaluate short periods of
402 frozen storage.

403 Overall, the duration of TIF (1, 6, 12 or 44 weeks) had no effect on most of the evaluated parameters
404 (Table 7), including pH_{4.6SN} ($P > 0.05$), ratio of soluble-to-total Ca ($P > 0.05$), LT_{max} ($P > 0.05$),
405 extensibility (EW₀, EW₅) ($P > 0.05$), Schreiber flow ($P > 0.05$) and sensory attributes ($P > 0.05$).

406 However, extending the storage from 12 weeks to 44 weeks reduced the firmness ($P < 0.001$) and
407 chewiness ($P < 0.001$) of the unheated cheese by 23% on average over the 30 d of total storage
408 time at 4°C, and reduced the COT ($P < 0.01$) of the heated cheese by 2% on average, i.e., the onset-
409 temperature for melting Mozzarella was reduced by 1.3°C. The reduction in melting point was not
410 reflected in the baking test, where panel members gave all TIF treatments similar scores for each
411 sensory attribute ($P > 0.05$) (Table 5). Moreover, the COT of TIF12 samples did not significantly
412 differ from those of TIF1, TIF6 or TIF44 samples ($P > 0.05$), which suggested that the effect of 44
413 weeks of frozen storage on the COT of frozen-thawed Mozzarella cheeses was limited.

414 Relative to the control, holding the cheeses at 4°C for 2 d before freezing to -20°C and keeping
415 them frozen for a period between 1 and 12 weeks did not influence the response variables ($P >$
416 0.05) (Table 7). However, when the cheeses were stored frozen for 44 weeks, firmness and
417 chewiness of cheeses were reduced by 29% ($P < 0.001$) and 26% ($P < 0.001$), respectively, whereas
418 the COT of the heated cheese was reduced by 1.7% ($P < 0.01$). Overall, freezing under these
419 conditions did not affect LT_{max} ($P > 0.05$), extensibility (EW_0 , EW_5) ($P > 0.05$), flow ($P > 0.05$) or
420 sensory attributes ($P > 0.05$) of the heated cheese.

421 3.3.3. Effects of time before freezing (TBF)

422 The TBF was varied in a systematic way to evaluate whether the potential detrimental effects of
423 direct freezing could be mitigated by prolonging the storage at 4°C before freezing and thereby
424 allowing the uptake of more-mobile-serum into the calcium-phosphate para-casein network of the
425 cheese (Kuo & Gunasekaran, 2003). Freezing as soon as possible after manufacturing could
426 minimize storage costs. Cheeses were held at 4°C for 0 (TBF0), 2 (TBF2) or 8 d (TBF8) before
427 freezing to -20°C; these cheeses were sampled from vats A and B (TBF0), vat C (TBF2) or vats D,
428 E, F and G (TBF8) (Table 3). Control cheeses, sampled from the different vats (A-G), differed in
429 terms of pH4.6SN ($P < 0.001$), cohesiveness ($P < 0.05$), springiness ($P < 0.01$), LT_{max} ($P < 0.001$)

430 and EW_0 ($P < 0.05$) after 16 d storage at 4°C, and differed in pH4.6SN ($P < 0.001$), firmness ($P <$
431 0.001), cohesiveness ($P < 0.05$), springiness ($P < 0.05$), LT_{max} ($P < 0.05$) and Schreiber flow ($P <$
432 0.01) after 30-37 d storage at 4°C, which implied that the effects of TBF were somewhat
433 confounded. Nevertheless, it was possible to compare each TBF treatment with the corresponding
434 control cheese from the same cheese vat (Table 3).

435 No significant differences were found between control cheeses, obtained from vats A or vat B, and
436 the corresponding frozen-thawed cheeses which were held at 4°C for 0 d before freezing to -20°C
437 (TBF0) (Table 5) (discussed in Section 3.3.1). A similar trend was found when comparing the
438 control and frozen-thawed cheeses from vat C (TBF2) (Table 5) (discussed in Section 3.3.2).
439 Likewise, TBF8 cheeses, obtained from 4 different vats, did not significantly differ from the
440 corresponding control cheeses ($P > 0.05$) (Table 5) with the exception of a significant interaction
441 effect between freezing and storage time at 4°C for firmness of the unheated cheese ($P < 0.01$).
442 Compared to the corresponding controls, TBF8 cheeses exhibited lower firmness after 10 d storage
443 at 4°C ($P < 0.01$), but not after other storage times ($P > 0.05$).

444 Overall, as evident from Fig. 3 and Fig. 4, the current results indicated that there was little effect
445 of holding the cheeses at 4°C for 0, 2 or 8 d before freezing to -20°C on the physicochemical and
446 functional properties of the current variant of LMPS Mozzarella.

447

448 **4. Conclusions**

449 A total of 132 blocks of LMPS Mozzarella cheese were sampled from a commercial manufacturer
450 over a 1.5 year period. The cheeses were assigned to 2 groups, namely control cheeses which were
451 stored at 4°C for up to 37 d, and frozen-thawed cheeses which were held at 4°C for different times
452 (TBF: 0, 2 or 8 d) before freezing to -20°C at different rates (FR: 0.6, 2.0 or 8.0°C h⁻¹). The frozen
453 cheeses were held at -20°C for different times (TIF: 1, 6, 12 or 44 weeks), and then placed at 4°C

454 for up to 37 d to achieve total storage times at 4°C similar to the control. The effects of freezing
455 were determined by comparing the control and frozen-thawed cheeses taken from the same vat,
456 and the effects of different freezing conditions (FR and TIF) by comparing the frozen-thawed
457 cheeses subjected to the different levels of condition. The control and frozen-thawed cheeses were
458 evaluated after similar total storage times at 4°C for composition, primary proteolysis, moisture
459 distribution, texture profile (firmness, springiness, cohesiveness), functional properties
460 (extensibility, viscoelastic behavior and flow of the heated cheese) and baking performance on
461 pizza. Overall, freezing *per se* did not significantly affect the properties of the cheese. Likewise,
462 there was little difference between frozen-thawed cheeses frozen under the following conditions:
463 FR (0.6, 2.0 or 8.0°C h⁻¹) or TIF (1, 6 or 12 weeks). Extending the TIF from 1, 6 or 12 weeks to 44
464 weeks reduced the firmness and chewiness of the unheated frozen-thawed cheese (by 23% on
465 average), and reduced the melting temperature by 2% during a total storage time at 4°C of 30 d.
466 However, there was no detectable difference in baking performance when the TIF was varied from
467 1 to 44 weeks.

468 Considering the overall effects observed in this study, we conclude that freezing of commercial
469 LMPS Mozzarella cheese (with respective dry matter, fat and protein levels of ~52, 22 and 25 g
470 100 g⁻¹, and a calcium level of ~740 mg 100 g⁻¹) under the applied conditions, halted the physico-
471 chemical changes that occur on storage at 4°C without having significant effects on functionality
472 and baking performance. However, the applicability of the findings to commercial Mozzarella in
473 general may vary depending on the manufacturing and compositional characteristics of the cheese,
474 which are likely to impact the degree of aggregation of the calcium-phosphate para-casein matrix
475 and its ability to bind serum. Critical factors affecting aggregation are likely to include cheese
476 moisture, pH, calcium content, ratio of soluble-to-total calcium, and degree of proteolysis. In
477 practice, changes in make procedure which affect cheese composition may therefore necessitate

478 tailoring of freezing conditions to ensure comparable functionality of control and frozen-thawed
479 Mozzarella.

480

571 (EW_5) min after melting and Schreiber flow of frozen-thawed LMPS Mozzarella cheeses, which
572 were held at 4°C for 0 (○), 2 (△) or 8 d (□) before freezing, and of corresponding control cheeses
573 (●, ▲ and ■). Trendlines represent the overall dynamic behavior of frozen-thawed (---) and
574 control (---) cheeses during storage at 4°C. The cheeses were obtained from 7 vats and frozen under
575 different conditions.

576
577 **Fig. 3:** Overall appearance of Mozzarella shreds after baking on a pizza after 2, 16 or 35 d of
578 storage at 4°C. Top row pictures present control Mozzarella and bottom row pictures present
579 frozen-thawed Mozzarella, held at 4°C for 0 days before freezing to -20°C. The cheese was held
580 frozen for 6 weeks. After freezing, cheeses were placed at 4°C for up to 35 d.

581

582 **Fig. 4:** Changes during storage at 4°C in pH 4.6 Soluble N, firmness, cross-over temperature
583 (COT), maximum value of the loss tangent (LT_{max}), extension work at 0 min after melting (EW_0),
584 and Schreiber flow of control and frozen-thawed LMPS Mozzarella cheeses, which were held at
585 4°C for 0 (TBF0) or 8 d (TBF8) before freezing to -20°C.

586 TBF0 samples, sampled from vat A or vat B, were used to determine the effects of holding the
587 cheese at 4°C for 0 d before freezing to -20°C (○); the cheeses were frozen at 0.6, 2 or 8°C h⁻¹ and
588 held in the freezer for 6 weeks. Control samples were taken from the same vat (○).

589 TBF8 samples, sampled from vat D, E, F or G, were used to determine the effects of holding the
590 cheeses at 4°C for 8 d before freezing to -20°C (□); the cheeses were frozen at 2°C h⁻¹ and held in
591 the freezer for 6 weeks. Control samples were taken from the same vats (□).

592 **Supplement A.** Overview of the sampling design per cheese vat.

593 Twenty-four cheeses were sampled from vat A. Six cheeses were control cheeses. Eighteen cheeses
594 were held at 4°C for 0 d before to freezing to -20°C (TBF0) at a rate of 0.6°C (FR0.6), 2.0°C
595 (FR2.0) or 8.0°C h⁻¹ (FR8.0) to evaluate the effects of freezing at different freezing rates (FR). All
596 cheeses were held frozen for 6 weeks (TIF6).

597 Forty cheeses were sampled from vat C. Eight cheeses were control cheeses. Thirty-two cheeses
598 were held at 4°C for 2 d before to freezing to -20°C (TBF2) at a rate of 2.0°C h⁻¹. The frozen
599 cheeses were held for 1 (TIF1), 6 (TIF6), 12 (TIF12) or 44 weeks (TIF44) in the freezer to evaluate
600 the effects of freezing at different holding times in the freezer (TIF).

601 To evaluate the effects of holding time at 4°C before freezing (TBF), cheeses from each vat were
602 subjected to one TBF condition. This approach ensured a similar sample size for each TBF
603 condition. A total of 24, 32 or 24 cheeses were held at 4°C for 0 (TBF0), 2 (TBF2) or 8 d (TBF8)
604 before freezing to -20°C, respectively. After freezing, cheeses were held at 4°C for up to 16 to 37

605 d, depending on the vat they were sampled from. Frozen-thawed cheeses (FT cheeses) and control
606 cheeses were evaluated at various storage times at 4°C (ST1, ST2, ST3 or ST4) (total storage time
607 at 4°C) as described in Table 3.

608 **Table 1: Experimental design to determine the effects of freezing at different rates (FR) on LMPS Mozzarella^{a,b}**

Control cheeses			Frozen-thawed cheeses						
Cheese vat	Number of cheese blocks	Storage time at 4°C (d)	Number of cheese blocks	Storage time at 4°C before freezing (d) (TBF)	Freezing rate (°C h ⁻¹) (FR)	Time in freezer (weeks) (TIF)	Storage time at 4°C after freezing (d)	Total storage time at 4°C (d)	Sample code
			6	0	0.6	6	4 - 12 - 37	4 - 12 - 37	FR0.6 TIF6 TBF0
Vat A	6	4 - 15 - 37	6	0	2.0	6	4 - 12 - 37	4 - 12 - 37	FR2.0 TIF6 TBF0
			6	0	8.0	6	4 - 12 - 37	4 - 12 - 37	FR8.0 TIF6 TBF0

609

610 ^aThe effects of FR were investigated by freezing 18 cheeses from vat A to -20°C at a rate of 0.6°C (FR0.6), 2.0°C (FR2.0) or 8.0°C h⁻¹
 611 (FR8.0). All cheeses were held at 4°C for 0 d before freezing (TBF0) and held in the freezer for 6 weeks (TIF6). After freezing, the
 612 frozen cheeses were placed at 4°C and stored at 4°C for up to 37 d.

613 ^bTo evaluate the effects of freezing on the characteristics of the cheese, frozen-thawed cheeses were compared to control cheeses after
 614 similar storage times at 4°C (total storage time at 4°C).

615 **Table 2: Experimental design to evaluate the effects of freezing at different storage times in the freezer (TIF) on LMPS**
 616 **Mozzarella^{a,b}**

Control cheeses			Frozen-thawed cheeses						
Cheese vat	Number of cheese blocks	Storage time at 4°C (d)	Number of cheese blocks	Storage time at 4°C before freezing (d) (TBF)	Freezing rate (°C h ⁻¹) (FR)	Time in freezer (weeks) (TIF)	Storage time at 4°C after freezing (d)	Total storage time at 4°C (d)	Sample code
Vat C	8	4 - 10 - 16 - 30	8	2	2.0	1	2 - 8 - 14 - 28	4 - 10 - 16 - 30	FR2.0 TIF1 TBF2

			8	2	2.0	44	2 - 8 - 14 - 28	4 - 10 - 16 - 30	FR2.0 TIF44 TBF2

617
 618 ^aThe effects of TIF were investigated by freezing 32 cheeses from vat C to -20°C and holding the cheeses in the freezer for 1 (TIF1), 6
 619 (TIF6), 12 (TIF12) or 44 weeks (TIF44). All cheeses were held for 2 d at 4°C before freezing (TBF2) and were frozen at a rate of
 620 2.0°C h⁻¹ (FR2.0). After freezing, the frozen cheeses were held at 4°C and kept at 4°C for up to 28 d.

621 ^bTo evaluate the effects of freezing on the characteristics of the cheese, frozen-thawed cheeses were compared to control cheeses after
 622 similar storage times at 4°C (total storage time at 4°C).

623 **Table 3: Experimental design to determine the effects of freezing at different storage times at 4°C before freezing (TBF) on**
 624 **LMPS Mozzarella^{a,b}**

Vat G	8	2 - 8 - 16 - 32	6	8	2.0	6	2 - 8 - 16	10 - 16 - 24	FR2.0 TIF6 TBF8

625
 626 ^aThe effects of TBF were investigated by holding: (i) 18 cheeses from vat A and 6 cheeses from vat B at 4°C for 0 d before freezing
 627 (TBF0), (ii) 32 cheeses from vat C at 4°C for 2 d before freezing (TBF2) and (iii) 6 cheeses from each of vats D, E F and G at 4°C for
 628 8 d before freezing (TBF8). All cheeses were frozen to -20°C at a rate of 0.6 (FR0.6), 2.0 (FR2.0) or 8.0°C h⁻¹ (FR8.0) and held in the
 629 freezer for 1 (TIF1), 6 (TIF6), 12 (TIF12) or 44 (TIF44) weeks. After freezing, frozen cheeses were held at 4°C for up to 16 to 37 d,
 630 depending on the vat they were sampled from. This approach ensured a similar sample size for each TBF condition.

631 ^bTo evaluate the effects of freezing on the characteristics of the cheese, frozen-thawed cheeses were compared to control cheeses after
 632 similar storage times at 4°C (total storage time at 4°C).

633 **Table 4: Composition of LMPS Mozzarella used in freezing studies**

Cheese vat	Dry matter (g 100g ⁻¹)	Fat (g 100g ⁻¹)	Protein (g 100g ⁻¹)	Salt (g 100g ⁻¹)	Calcium (mg 100g ⁻¹)	pH
A	52.1 ^{a,b}	21.7 ^a	24.4 ^a	0.9 ^a	766 ^{a,b}	5.53 ^a
B	52.6 ^b	21.8 ^{a,b}	25.3 ^a	1.2 ^{b,c}	809 ^a	5.51 ^a
C	52.0 ^{a,b}	21.7 ^a	24.8 ^a	1.1 ^b	697 ^c	5.41 ^{b,d}
D	52.0 ^{a,b}	22.1 ^c	24.5 ^a	1.1 ^b	712 ^{b,c}	5.43 ^b
E	51.9 ^{a,b}	21.7 ^a	25.1 ^a	1.2 ^b	696 ^c	5.34 ^c
F	52.2 ^{a,b}	22.1 ^{b,c}	24.8 ^a	1.3 ^c	735 ^{a,b,c}	5.34 ^c
G	51.7 ^a	21.6 ^a	24.7 ^a	1.3 ^c	784 ^a	5.36 ^{c,d}

634 ^{a,b,c} Values in columns with different superscripted letters denote a significant difference ($P < 0.05$). Presented data of dry matter, fat,
 635 protein, salt and calcium content are mean values measured on at least four different cheeses per vat. The pH of the cheese was
 636 measured on two cheeses per vat after 2 d of storage at 4°C.

637 **Table 5: Effects of freezing treatments (FR, freezing rate; TIF, storage time in freezer; TBF, storage time at 4°C before**

639 ^aThe statistical significance (*P*) for treatment effects across the evaluated properties of control and frozen-thawed cheeses is given where
 640 *P* > 0.05, *P* < 0.05, *P* < 0.01 and *P* < 0.001 is denoted by -, *, ** and ***, respectively.

642 ^bThe effects of freezing (Fr) were determined by comparing the characteristics of the control and frozen-thawed cheeses.

643 ^cThe effects of total storage time at 4°C (ST) were determined for all cheeses. Cheeses were stored at 4°C for up to 37 d.

644 ^dCheese treatments where cheeses were held at 4°C for 0 d before freezing to -20°C (TBF0) correspond to cheeses frozen at a rate of 0.6,
645 2.0 or 8.0°C h⁻¹. The frozen cheeses were held frozen for 6 weeks in the freezer. Control and frozen-thawed cheeses were sampled from
646 vats A or B.

647 ^eCheese treatments where cheeses were held at 4°C for 2 d before freezing to -20°C (TBF2) correspond to cheeses frozen at a rate of
648 2.0°C h⁻¹. The frozen cheeses were held frozen for 1, 6, 12 or 44 weeks in the freezer. Control and frozen-thawed cheeses were sampled
649 from vats C.

650 ^fCheese treatments where cheeses were held at 4°C for 8 d before freezing to -20°C (TBF8) correspond to cheeses frozen at a rate of
651 2.0°C h⁻¹. The frozen cheeses were held frozen for 6 weeks in the freezer. Control and frozen-thawed cheeses were sampled from vats
652 D, E, F or G.

653 ^gn/d = not determined; n/a = not applicable

656

657 ^aThe statistical significance (*P*) for treatment effects across the evaluated properties of LMPS Mozzarella is given where $P > 0.05$, $P <$
658 0.01 and $P < 0.001$ are denoted by -, ** and *** respectively. Control and frozen-thawed cheeses were sampled from vat A.

659 ^bThe different cheese treatments correspond to cheeses frozen to -20°C at 0.6 (FR0.6), 2.0 , (FR2.0) or $8.0^{\circ}\text{C h}^{-1}$ (FR8.0). The frozen
660 cheeses were held at 4°C for 0 d before freezing and held in the freezer for 6 weeks.

661 ^cThe different storage times at 4°C (total time at 4°C) correspond to: 4 d (storage time 1), 12-15 d (storage time 2) or 37 d (storage time
662 3) with the exception for the characteristic more-mobile-serum, which was analyzed at 2, 4 or 9 d storage at 4°C

663 ^dData presented are means \pm standard deviation of two Mozzarella blocks per ripening point.

666

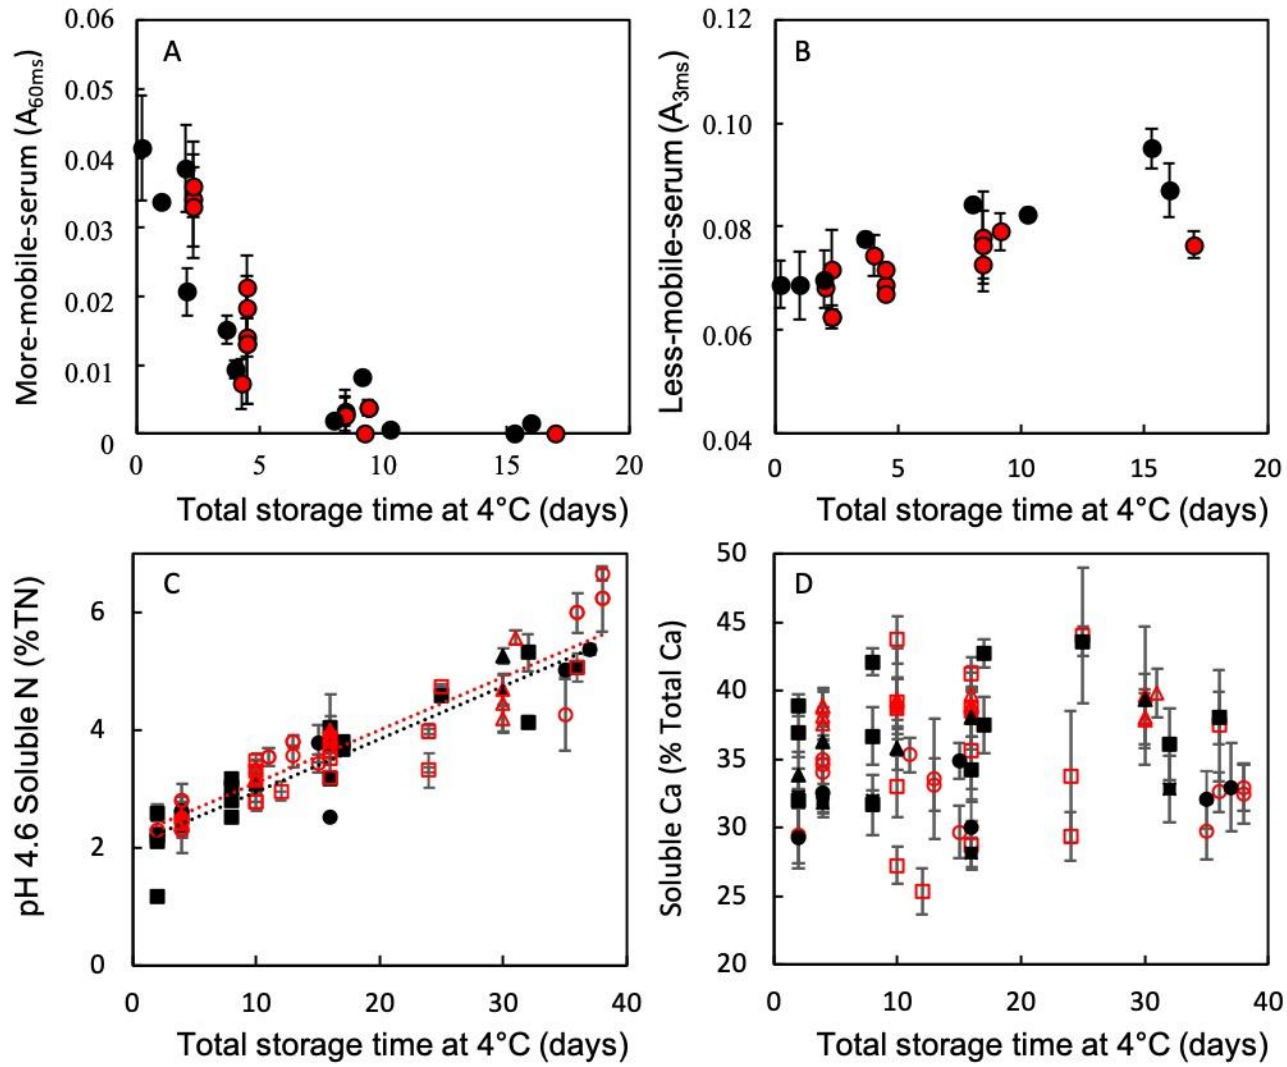

667 ^aThe statistical significance (*P*) for treatment effects across the evaluated properties of LMPS Mozzarella is given where $P > 0.05$, $P <$
668 0.05 , $P < 0.01$ and $P < 0.001$ are denoted by -, *, ** and ***, respectively. All cheeses were sampled from vat C.

669 ^bThe different cheese treatments correspond to cheeses stored frozen for 1 (TIF1), 6 (TIF6), 12 (TIF12) or 44 (TIF44) weeks. The cheeses
670 were held at 4°C for 2 d before freezing to -20°C at a rate of 2°C h⁻¹.

671 ^cThe different storage times at 4°C (total time at 4°C) correspond to: 4 d (storage time 1), 10 d (not included in table), 16 d (storage time
672 2) or 30 d (storage time 3).

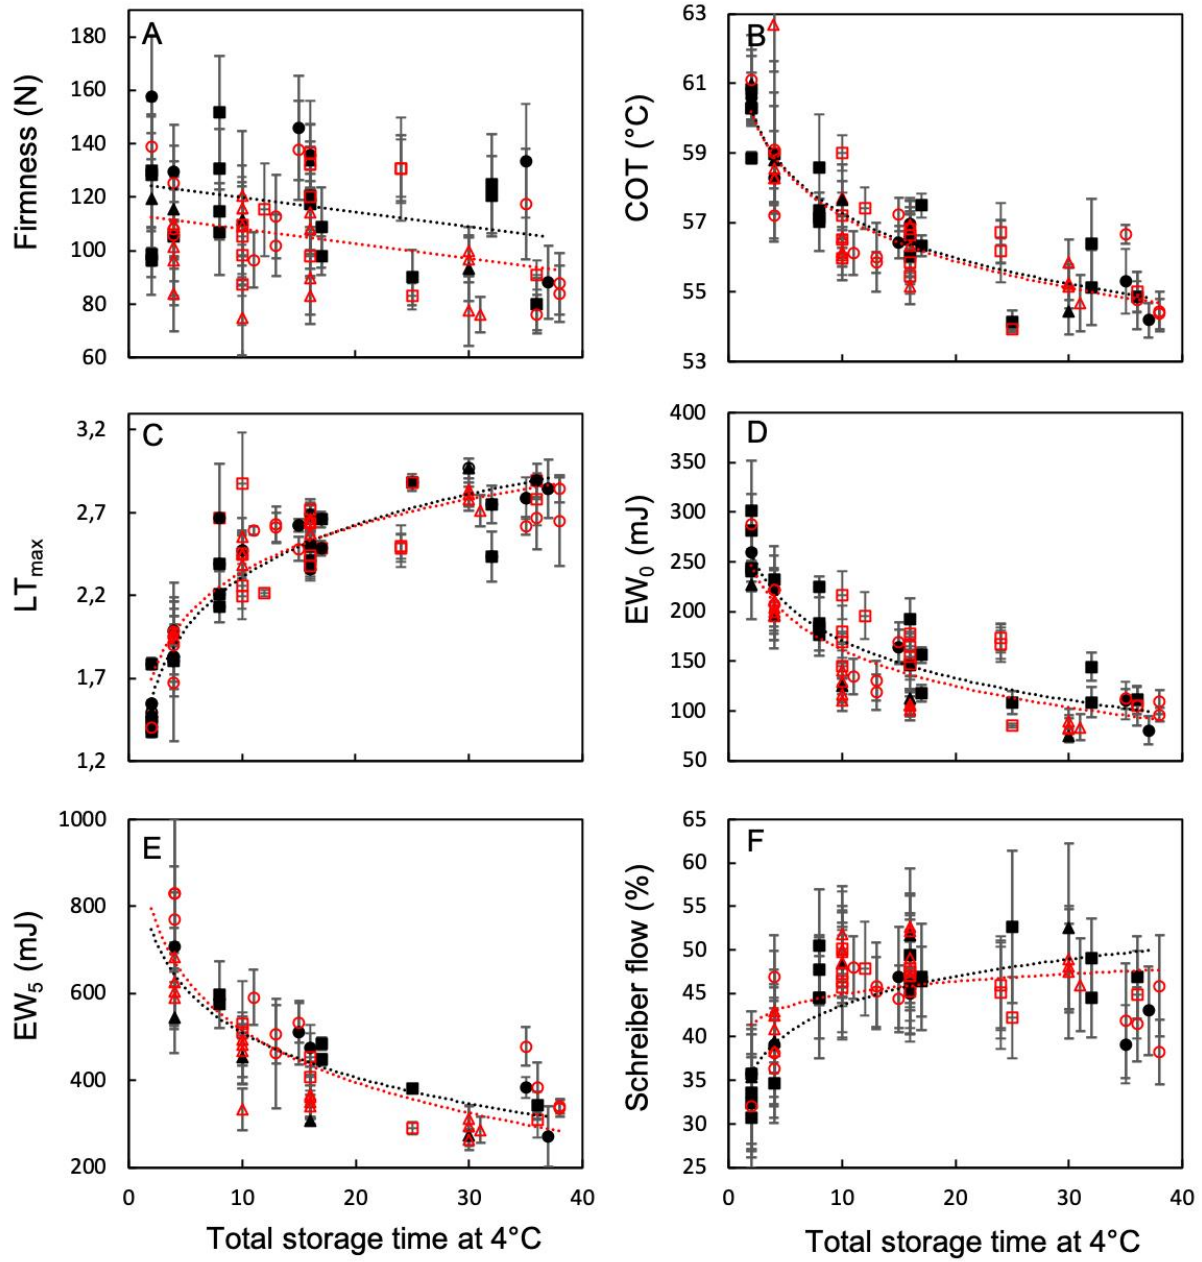

673 ^dData presented are means ± standard deviation of two Mozzarella blocks per ripening point.
