Vaccine hesitancy and access to psoriasis care during the COVID-19 pandemic: findings from a global patient-reported cross-sectional survey

DOI: 10.1111/bjd.21042

Dear Editor, COVID-19 vaccines protect against severe COVID-19 outcomes; however, many individuals remain unvaccinated.1,2 Vaccine hesitancy (delayed acceptance or refusal of vaccination despite service availability) threatens public health. In the UK general population, vaccine hesitancy is higher in women, younger people and ethnic minority groups.3,4 Individuals with psoriasis, particularly those taking systemic immunosuppressants, are prioritized for COVID-19 vaccination.5 However, information on vaccine hesitancy and its contributing factors in patients with psoriasis is scarce.6

We used data from the global patient-reported PsoProtectMe survey7 to explore the impact of organizational and individual factors on COVID-19 vaccine hesitancy. Data from 802 individuals with psoriasis from 89 countries were available (extracted 9 August 2021). Overall, 322 (40.1%) reported disrupted access to psoriasis care. These individuals were younger [median age 44 years, interquartile range (IQR) 33–56 vs. 54 years, IQR 42–64] and more likely to be of non-white ethnicity (13.8% vs. 10.2%) than those reporting no disruption. They had a shorter duration of psoriasis (median 23 years, IQR 10–36 vs. 31 years, IQR 17–44) and more severe psoriasis (6.1% vs. 2.8%). The proportion of participants taking systemic immunosuppressants was similar between those with and without disrupted access to care, but a smaller proportion with disrupted care were taking targeted immunosuppressants than those without disruption (72 of 131, 55.0% vs. 140 of 194, 72.2%).

In total, 611 (80.9%) of 755 participants had received at least one vaccine dose; 99 (16.2%) reported worsened psoriasis following vaccination, with 63 describing changes within 2 weeks. Sixty-three (8.3%) were vaccine hesitant. These individuals were younger (median age 36, IQR 30–50 vs. 52, IQR 39–63), and more likely to be of non-white ethnicity (20% vs. 7.2%), live outside the UK (14% vs. 5.1%), have a numerically lower body mass index (median 24.5 kg m−2, IQR 21.7–28.3 vs. 26.5 kg m−2, 23.2–30.9) and have a shorter disease duration (median 19 years, IQR 9–32 vs. 28 years, IQR 14–42) than those who were not hesitant (Figure 1a–c). They were less likely to be taking systemic immunosuppressants (26% vs. 45.3%). The most common reasons for hesitancy were concerns regarding side-effects, the vaccine being new and psoriasis worsening postvaccination.

In an unadjusted logistic regression model, strongly agreeing that psoriasis care was disrupted, was associated with vaccine hesitancy [compared with strongly disagreeing; odds ratio (OR) 2.97, 95% confidence interval (CI) 1.23–7.13, P = 0.015]. The direction of association remained after adjusting for age, sex and ethnicity, although this was not statistically significant (adjusted OR 1.90, 95% CI 0.72–5.05) (Figure 1d). In the imputed multivariate model (fitted due to missing demographic data), the association was stronger but not significant (adjusted OR 2.32, 95% CI 0.94–5.71). In total, 56 of 320 (17.5%) individuals taking standard, targeted or combination immunosuppressants were nonadherent. Non-adherence and vaccine hesitancy were not significantly associated (adjusted OR 2.96, 95% CI 0.77–11.3).

We observed an association between disrupted access to psoriasis care and COVID-19 vaccine hesitancy, partly mediated by confounding demographic variables. Individuals feeling disenfranchized by healthcare services were more likely to be vaccine hesitant. In keeping with this finding, higher vaccine hesitancy in the general population is observed in those with negative experiences of healthcare and negative perceptions of doctors.4 Higher care expectations, sometimes seen in individuals with worse disease,5 may also be contributory. Patients taking targeted immunosuppressants were less likely to report disrupted access to care, possibly due to more frequent monitoring in secondary care, which may have been prioritized during the pandemic.

A minority (8%) of our sample reported vaccine hesitancy. This finding supports current limited data on vaccine hesitancy among patients with psoriasis.5 In contrast to a prior report in psoriasis,4 but in keeping with general population trends,4 hesitancy was more prominent among younger people. Our study was conducted after the COVID-19 vaccine rollout commenced, addressing a limitation of studies characterizing intention rather than actual behaviour.5 In keeping with other studies, our findings also indicate greater hesitancy in individuals of non-white ethnicity; however, there were no differences by sex.4

We are unable to directly compare our global psoriasis dataset to the general population or groups with other diseases due to a lack of control samples. Participants were mostly from the UK, female and of white ethnicity, limiting generalizability. Proportionally more patients reported receiving targeted vs. standard immunosuppression, indicating ascertainment bias. Directions of associations cannot be
definitely ascertained due to the cross-sectional study design. Impacts on care and/or vaccine uptake may have been underestimated as individuals participating in health surveys may be more engaged with healthcare and vaccination services. PsoProtectMe was updated 1 year following its launch to include COVID-19 vaccine hesitancy and questions regarding access to care, hence the current sample may not be representative of the original larger sample.7

Taken together, these data indicate that only a minority of individuals with psoriasis have vaccine hesitancy hence our findings are promising for current and future COVID-19 vaccine uptake. Identifying individuals who are disenfranchised

Figure 1 COVID-19 vaccine hesitancy in individuals with psoriasis: (a) overall count, (b) by age and ethnicity (age < 31 years n = 93, 31–50 years n = 219, 51–70 years n = 261, > 70 years n = 58; white ethnicity n = 559, nonwhite ethnicity n = 70) and (c) by systemic immunosuppressant therapy (no therapy n = 406, standard therapy n = 110, targeted therapy n = 207). (d) Association between disrupted access to psoriasis care and COVID-19 vaccine hesitancy.

Reference group: ‘strongly disagree’
by healthcare services and addressing their concerns regarding COVID-19 vaccination will help mitigate risks from the ongoing pandemic.

Acknowledgments: We are extremely grateful to all the patients who have contributed to PsoProtectMe, the professional and patient organizations who supported or promoted PsoProtectMe, and Professor Lars Iversen, Professor Nick Reynolds and Professor Joel Gelfand for their valuable input. We would like to acknowledge the following individuals for help with translating the PsoProtectMe survey: Dr Haleema Alfaiakawi, Dr Wisam Alwan, Dr Rosa Andres Ejarque, Dr Ines Barbosa, Ms Carmen Bugarin Diz, Ms Katarzyna Grysz, Dr Mahira Hamdy El Sayed, Mr Tran Hong Truong, Mr Masanori Okuse, Ms Dagmara Samelska, Ms Isabella Tosi and Ms Ya-Hsin Wang. Thank you to the Engine Group UK for their generous creative input and website expertise.
